Dr. John V. Shoemaker offered a resolution that it was the sense of the Medical Society of the State of Pennsylvania that the physicians and surgeons in attendance upon our late Chief Executive, William McKinley, acted in accordance with the dictates of the best medical and surgical science and that they had the full confidence of the Society.

Address in Surgery—Torsion of Arteries.

Dr. James W. MacFarlane considered the arrest of hemorrhage, particularly that by torsion. He divided torsion into two forms: limited, and free. In so far as the general public is concerned, he said, free torsion is the rule, as limited is not so advantageous. When free torsion fails primarily in a large artery, it is not limited torsion that is required, but the ligature, acupressure and perhaps the complete hemostatic armamentarium of the surgeon. In the matter of time, and the absence of danger of introduction of a foreign body into the wound, torsion is also superior. Another advantage is that an assistant is not required. Torsion in amputations was introduced into the Western Pennsylvania Hospital, Pittsburg, about 1870. Even atheromatous arteries are no bar to its use. The most probable cases in which torsion would not answer are in amputations contiguous to tissues changed by chronic inflammations. Torsion will not prevent secondary hemorrhage and the speaker cited a case in which infection occurred as the cause of secondary hemorrhage; after amputation torsion was again employed and recovery ensued. Exceptional cases were cited in which acupressure was superior to ligature or torsion.

The Operative Treatment of Bladder, Descent and Sacculation.

Dr. George Erety Shoemaker, Philadelphia, said that displacements of the bladder in the female may take place upward, backward, laterally, forward, or downward. Only in the downward direction is sacculation and imperfect evacuation liable to occur frequently, but its secondary effects are very important. He has seen but one case of pathologic forward dislocation. The various displacements with their symptoms were described. Operations above the pubis have little effect upon the bladder position if unsupported by other measures. The plan adopted by the writer was given in detail. Special attention was called to the method of taking up the redundant anterior vaginal wall and supporting the bladder.

The Present Status of the Bottini Operation as a Method of Treatment in Obstructive Hypertrophy of the Prostate Gland, Derived from a Summary of 834 Operations by 48 Operators.

Dr. Orville Horwitz said that contrary to the accepted view that prostatic hypertrophy usually began in individuals over 50 years of age, he believes that the morbid condition commences much earlier, and quotes Dr. L. Bolton Bangs, who agrees with him. Regarding the objection to the Bottini operation held by some, he thought the recorded experience of trustworthy surgeons gave sufficient refutation of the charges that this operation is "uncertain, dangerous and the results obtained are temporary in character." The operation of complete prostatectomy is considered a much more formidable undertaking than that of the Bottini; it is fraught with greater danger, and only to be attempted in rare instances. He thought it worthy of note that the writers objecting to the Bottini operation on the theoretical grounds, had the least practice with the method. In none of the cases under Dr. Horwitz's care has contraction of the vesical outlet, a complication suggested by some, occurred. Pyelitis, though adding to the danger, is not a contra-indication. Four such cases have been operated. Age is not a bar, though the mortality is lower when the resisting power is strong. Statistics of the 843 Bottini operations were given, with a series of conclusions.

Surgery and Its Relation to Neurasthenia.

Dr. G. D. Nutt, Williamsport, stated that in a large number of patients, prominent symptoms of a neurotic character, caused by disease, displaced or irregular muscular action of some organ, can be cured by surgical means. Examples of this class are diseases of the sexual organs, movable kidney, errors of refraction and muscular insufficiency of the recti muscles of the eye. In many cases of neurasthenia correction of abnormal conditions affecting the nervous system must precede the medical treatment. Since pathologic conditions cause nervous symptoms not directly connected with the affected organs, the question was raised, might there not be other diseased organs causing reflex disturbance yet unknown, to account for the large and increasing number of neurasthenics?

Rare Complications in Appendicitis with Their Treatment.

Dr. Ernest Laplace, Philadelphia, presented cases in which these complications had existed. They had a history of a previous acute attack, cured by medical measures, with, however, remaining obscure abdominal pain. Such cases had been erroneously diagnosed as affections of nearly every organ in the abdomen. In view of the difficulty in absolute diagnosis, the necessity of proper surgical intervention was pointed out. Particularly is this necessity apparent when it is realized that pain may be absent in acute appendicitis, or felt at a totally different spot; that fever may be absent, or range to 104 or 105; that a general disturbance and local rigidity are perhaps the only constantly present symptoms of the disease. In every case of appendicitis it should be borne in mind that there was a time when operation would have saved life.

Dr. Joseph Price made the statement that "more people are dying to-day of appendicitis than from an epidemic of smallpox." Chronic cases ought never to occur. Well-marked symptoms, late in the cases, evidenced the fact that the early symptoms should have been detected by a good clinician. He believed the public would come to hold the clinicians thrice responsible for early diagnoses. The complications mentioned in Dr. Laplace's paper should have been prevented by proper recognition of the early conditions.

Dr. Adolph Koenig, Pittsburg, said that he was a general practitioner and as such believed that the general practitioner should use good judgment. He had been in practice twenty-two years and had never yet lost a case of appendicitis which he had had from the beginning. If he saw that a case was not improving under medication he would call in a surgeon, but asserted that a surgeon had no right to operate in a mild inflammatory condition mistaken for appendicitis.

Dr. Mordecai Price reinforced the sentiments of the paper and the expressions of Dr. Joseph Price. His common experience of meeting physicians who had never seen a case of appendicitis, he thought, was explained by the fact that the condition was not recognized. In almost any intraperitoneal inflammation you can safely operate for appendicitis.

Dr. Laplace, in closing, said that inasmuch as the complications are numberless and the diagnosis is often difficult, the patient should be given the benefit of the doubt and the chance of recovery from immediate operation. If the appendix could be purged of its offensive material by drastic measures this should be done. Should the pain reappear after having disappeared, nothing could do justice but the knife. If everybody were rightly treated we would not hear of a case of appendicitis. An "unsuccessful operation" meant that somebody had blundered; the medical man had treated too long, or the surgeon has been a "dirty" surgeon. With the present understanding of appendicitis, the patient should live.

A Case of Perforating Typhoid Ulcer; Laparotomy; Recovery.

Dr. W. L. Rodman, Philadelphia, reported a case of perforating typhoid ulcer in the fifth week, followed by extensive general peritonitis, with an operation thirty-seven hours after the accident. The perforation was found directly under the incision. It was as large as the end of a finger and there was considerable extravasation into the cavity. The opening was rapidly closed with Lembert sutures, and the cavity was flushed with hot saline solution. A large amount of iodoform gauze was introduced at the upper end of the incision, and carried carefully down to and around the perforation, so as to

protect the cavity from further possible infection, and also to facilitate drainage. A drainage tube was introduced at the lower end of the wound. Although the case was *in extremis*, with a pulse that could not be counted, the abdomen being like a tightly distended drum, the patient made an unexpected recovery, that is, to-day is perfectly well. The gauze was removed on the tenth day, portions of it having been withdrawn several days earlier. The drainage tube was removed at the end of the sixth day. Time of operation from beginning to end was sixteen minutes. Ether was used as an anesthetic. Dr. Rodman's impressions from this case were: 1. That a case of perforation, even though general peritonitis had begun, should be given the benefit of a laparotomy, if in a hospital where such work can be done with reasonable dispatch. This operation was done at least thirty-seven hours after the perforation. There have been, according to Keen in his monograph, but two successful cases reported where so great a time had elapsed between the accident and the operation, and one of these is doubtful, inasmuch as the perforation was not found. There could be few seemingly more desperate cases than this one, and this, together with a case of general peritonitis following a gunshot wound of the intestine and operated upon successfully fifty-one hours after the accident, has shown that it is rarely too late to give such cases the benefit of surgery. 2. That general anesthesia can be borne even in as grave a condition as this patient was in at the time of operation; she was practically pulseless. Cocain was considered at the time, but the patient was too young to give intelligent co-operation, so necessary for the performance of a laparotomy in the shortest possible time. A third question which might be raised is, how frequently will pathologic perforations of the gut in typhoid fever repair themselves without surgical intervention? Recovery does occasionally take place; the percentage has been estimated to be between 3 and 10 per cent. A much larger number will recover from operation and intervention is indicated. While it may be undoubtedly proper to decline interference in military practice on account of the limited facilities in field hospitals, the rule of action should be just the opposite in civil practice. There is an analogy between traumatic and pathologic perforations of the intestines, not complete, but involving the same general principles, and their treatment should be similar, namely, perform laparotomy as early as is consistent with the existing shock. It is as much a duty to operate in both conditions as it is to tie a bleeding vessel in hemorrhage.

Dr. Joseph Price considered the operation in this case the acme of good surgery.

Dr. Ella B. Everitt, Physician-in-Charge at the Woman's Hospital, said that it had been with the greatest interest that she had watched the case. Drainage from the tube was continued for a week after the operation and drainage from gauze a day or two later. Pus cells were present, but no active organisms were found. She thought the lesson was evident that such patients were entitled to operative interference even though, as was this child, almost moribund. The severity of the attack was so great that it seemed that the child could hardly have lived even without this grave operation. The result was doubly gratifying. The occurrence of a small hemorrhage after the operation was also noted as a second complication. The child rallied well from this and went on to a satisfactory recovery.

Dr. Elizabeth Bundy said the point of interest to her was the range of the persistent temperature. The condition of the child had begun to improve within an hour from the time of the accident.

A Case of Ascites Due to Syphilitic Cirrhosis of the Liver.

Dr. W. J. Roe, Philadelphia, presented the report of this case. Seventeen months after the beginning of ascites, and fourteen months after the first paracentesis, he transplanted the omentum between the perietal peritoneum and the abdominal wall, suturing the omental border of the stomach and colon to the margins of the artificial pocket. Previous to operation, paracentesis was performed 31 times, with an average of 760 ounces and of 14 days' interval. Subsequent to operation, it was performed 21 times; the average was 218 ounces and 12 days' interval. Marked improvement in her general health ensued. After six months her general condition reverted to that at the time of operation and death occurred at the end of eight months. Autopsy showed extensive vascular adhesions, a horseshoe kidney and syphilitic cirrhosis of the liver.

THIRD DAY—AFTERNOON SESSION.

Address in Obstetrics.

Dr. David Funk, Harrisburg, presented the status of several of the more serious obstetric complications and operative procedures. From the standpoint of the general practitioner it was stated that placenta previa would probably remain one of the most disquieting and alarming complications, because there can be no prophylaxis and because of the appalling rapidity with which it destroys life. Symphysiotomy as an operation of election would appear to be gradually displaced by Cesarean section, where the high forceps operation is dangerous. Puerperal septicemia and ectopic gestation were considered in detail. The responsibility of the general practitioner in making an early diagnosis in ectopic gestation, is emphasized. Points of differential diagnosis are as follows: Previous history of sterility; cessation of previously regular menstrual periods; irregular bleeding; colicky pains, and nausea and vomiting. Puerperal eclampsia with its etiology and treatment was considered. As to the etiology, writers are agreed upon a single point—toxemia; in the treatment, serum therapy is regarded as a problem of the future.

The Ultimate Results of Operation for Cancer of the Uterus.

Dr. Charles P. Noble, Philadelphia, emphasized the fact that the greatest problem confronting the medical world is the causation and cure of cancer. In a review of the recent American, French and German literature, it was shown that hysterectomy for cancer of the cervix cures about 10 per cent. of cases; based upon the standpoint of freedom from recurrence at the end of five years, the figures of different surgeons varying from a percentage of zero to twenty of cures. Hysterectomy for cancer of the body of the uterus gives better results, at least 75 per cent. being cured. The writer reports 32 cases of hysterectomy for cancer. Of these 10 have died of recurrence and 1 of pneumonia; 6 cases have been lost sight of, and 2 cases of cancer of the cervix are known to have recurred. The remaining 13 are free from recurrence at the present time. The hope for improvement in results lies in early diagnosis. The fallacy of the doctrine of climacteric hemorrhages is insisted upon, and it is strongly urged that all cases with irregular discharges would be promptly investigated.

Instrumental Perforation of the Uterus.

Dr. Wilmer Krusen, Philadelphia, discussed the conditions which soften the uterus and render the accident liable—carcinoma, anemia, tuberculosis and subinvolution. The different perforations are enumerated with the results. He reported a case of perforation of the uterus at the fundus, in which the omentum had been caught by the curette and drawn through the uterus into the vagina. He saw the case within two hours after the accident and immediately performed celiotomy, with an interrupted recovery. He emphasized the necessity for care, cleanliness and special training in all intrauterine manipulations.

Some Surprises in the Practice of Obstetrics.

Dr. R. B. Ewing, West Grove, reported a series of obstetric cases interesting from the fact that the unexpected occurred. They were illustrative of the terse expression of one of the most gifted medical authors and teachers of America, who after a lifetime of active service as an obstetrician said: "The practice of obstetrics is full of surprises."

A Parasitic Skin Disease.

Dr. John V. Shoemaker, Philadelphia, exhibited a patient with a peculiar parasitic disease of the skin. Some of its characteristics are its appearance between the ages of 20 and 40,

being found by preference upon the anterior portion of the chest, appearing as somewhat irregular patches. It differs from liver spots in that the cause is from without the body, the parasite is conveyed from water or from decayed vegetable material. Sometimes clean linen will contain the germs. He recommended the use of the ordinary corrosive sublimate, the copper salts whether in sulphate or the oleate, and mercury in the form of ointment as the oleate of mercury. He especially emphasized the fact that water should not be used; alcohol, or alcohol in the water should be applied.

A Remarkable Case of Infantile Typhoid of Fetal Origin with Recovery.

DR. HARRY C. WESTERVELT, Pittsburg, reported the case of a woman seven months pregnant with the third child, who had typhoid fever. The child was delivered at seven months and the mother had a severe course of the fever, but made a good recovery. The child presented the characteristic "old man" appearance of the prematurely born, and weighed 9 pounds, 14 ounces. A temperature of 103.4 F. soon appeared. The fever ran the regular course; the child recovered and presents every appearance of a healthy babyhood.

The Effects of Typhoid Fever on the Nervous System.

DR. C. C. HERSMAN, Pittsburg, considered impure air, food, and water the most frequent causes of typhoid fever. In the majority of cases the nervous system is the first attacked by the poison. Not infrequently is the cardiac ganglion and nerve supply of the heart in general supercharged with the poison. The resulting symptoms were given in detail and the convalescence described. Meningitis was mentioned as a grave complication. Two such cases had been treated by the writer within the past two years, one of which recovered. Friedlander, Berlin, was quoted as giving 80 per cent. mortality in typhoid meningitis. Tubercular predisposition in children was mentioned as a fruitful source of typhoid meningitis.

The Value and Importance of Teaching the Fundamental Branches of Medicine from the Standpoint of Their Practical Application.

DR. GWILYM G. DAVIS emphasized the fact that teaching should be conducted so that the student understands his subject instead of simply knowing isolated facts. Medicine, it was said, requires too much of a man to enable him to qualify by simply memorizing his subject. Text-books are too statistical and not sufficiently explanatory. Examiners should avoid catch questions and give such that require an understanding of the subject for their answer.

To teach the student to think, not summarize, is the object. The day of the true pedagogue, though long delayed, is at last dawning.

Ruptured Tubal Gestation and the Physician.

DR. JOHN M. FISHER, Philadelphia, stated that no form of acute supravaginal pelvic disorder is fraught with more immediate danger to the life of the individual, and yet none in the vast majority of cases is more readily diagnosticated by the experienced gynecologist, and none can be more satisfactorily dealt with by the surgeon than that of ectopic pregnancy. The diagnosis being made, prompt surgery, with but few exceptions, saves the patient. With comparatively few exceptions Dr. Fisher stated that the condition is tubal. The causes are enumerated and the symptoms described. In the light of the perfected methods in surgical technic of the present day the author declares that so-called conservative plans are not to be considered, save in so far as they add to the ever-increasing number of unfortunates to our mortality statistics.

The Kidney Complications of Typhoid Fever.

DR. JAMES ELY TALLEY, Philadelphia, in this paper enumerated these complications as albuminuria, acute parenchymatous nephritis, hemorrhagic nephritis and suppurative nephritis. In a series of over 15,000 cases albuminuria occurred in 29 per cent. of cases. Acute parenchymatous nephritis occurred in 3 per cent. of a series of over 18,000 cases with a mortality of from 30 to 50 per cent. Edema is rarely produced, and, if the patient lives, the nephritis almost never becomes chronic; only two such cases are recorded in over 37,000 cases of typhoid. Hemorrhagic nephritis is defined as but an aggravated form of the acute parenchymatous nephritis. It tends strongly toward uremia and has a very large mortality. Suppurative nephritis occurs occasionally, and in these cases typhoid bacilli have been found frequently in the pus or kidney substance at postmortem. If chronic nephritis exists and typhoid intervenes the mortality is very high, over 90 per cent. Albuminuris and acute nephritis occur in the typhoid fever of children with about the same frequency as in adults.

New Method of Performing Nephropexy.

DR. HENRY D. BEYEA, Philadelphia, described in full the surgical treatment. The operation is indicated only in those cases where the pathologically mobile kidney produces a complex of symptoms inducing persistent ill-health, and the prescribed medical and mechanical treatment either fails to give relief, or, in the judgment of the physician, is impracticable from the beginning.

Statistics of Typhoid Fever at the Philadelphia Hospital from Jan. 1, to Dec. 1, 1899.

DR. HERMAN B. ALLYN gave the following statistics: Whole number of cases 184; 135 were males and 49 females; 146 were white and 38 black or mulattoes. The fatal cases numbered 31, a mortality of 16.84 per cent., accounted for largely by the character of the patients and stage of the disease at the time that they were admitted. The patients were made up of the homeless, neglected, dissipated and outcast. Half the fatal cases occurred in negroes, although they constituted only about one-fifth of the whole number of cases. Moreover, only one-fifth of the fatal cases—6—were admitted during the first week, and 23 after the disease had lasted two weeks or more. The causes of death, following Osler's classification, were: Asthenia, 14; intercurrent affections, 9; accidents of the lesion, 8. The Gruber-Widal serum reaction was in accord with the final clinical diagnosis in 88 per cent. of the last 113 cases.

Fracture of the Neck of the Femur—Report of a Case, X-Ray and Specimen.

DR. CHARLES E. THOMSON, Scranton, reported the case of a patient, aged 62, who sustained a fracture in August, 1899. The patient was bedridden for three months. The shortening amounted to two and one-half inches and the hip was very painful. The operation was described. A solid silver nail, three-sixteenths of an inch in diameter and two and one-half inches long, was driven through the neck and into the head of the femur. The bone flap was replaced and retained by a small silver nail. One year after operation the patient had three-quarters of an inch shortening with 90 degrees free and painless motion. Death occurred from intercurrent disease six months later. The specimen showed firm bony union.

The Pathology, Symptomatology and Treatment of Uremia.

DR. DAVID RIESMAN, Philadelphia, presented a very valuable paper devoted to a portrayal of certain less common forms of uremia, namely, uremia associated with hemiplegia, aphasia, mental confusion and insanity. Two points in the treatment were emphasized: bleeding, and sweating. The patient is put into a hot bath of 110 F. for ten minutes, taken out and then put into a hot pack for twenty minutes.

The Etiology of Acute Dysentery.

DR. SIMON FLEXNER, Philadelphia, said that reports of bacteriologic work in the tropics, Japan, Germany and this country on the etiology of acute dysentery, agree that there is present a septic organism quite peculiar and not found in the body under normal conditions, which seems to be present uniformly when cases of acute dysentery arise. The fact is a matter of importance in respect to the causation of this serious disease and to its prevention. It would appear that the sporadic cases have the same origin as the acute dysentery, and this is of particular importance in the consideration of epi-

demics. The micro-organism that has been discovered is the organism bearing more or less resemblance to the bacillus of typhoid fever. It occurs in the intestines and can be obtained from the dejecta. It does not occur in health or in other diseases; moreover, the blood serum will give a reaction similar to the Widal reaction. It seems probable, therefore, that, as a result of this work, the septic organism of acute dysentery has been observed. It does not exclude the amoeba. It is possible by the use of this organ to produce serum that may be curative.

In Closing.

Dr. F. B. Ball, the new president, was introduced by Dr. Davis, who welcomed him in a few graceful words. After a short address by Dr. Ball, and a resolution of thanks to all those who had participated in the arrangements for the pleasure of the Society and the success of the meeting, offered by Dr. Alexander Craig, Columbia, the meeting was declared adjourned. The next meeting will be held at Allentown.

CHICAGO ACADEMY OF MEDICINE.

Regular Meeting, held September 13, 1901.

Dr. W. X. Sudduth in the Chair.

Forensic Eye Aspect of Locomotor Ataxia.

Dr. James G. Kiernan presented a paper on this subject. A recent suit against the Chicago Union Traction Company was based upon a diagnosis, made of locomotor ataxia, chargeable to an alleged traumatism occurring fourteen days previous to examination, from an alleged condition of the pupils of which no clear description was given. The diagnostician (a member of the family) had observed the pupils under disadvantageous conditions. From his testimony it would appear that this physician had a crude notion that there was reflex iridoplegia or the Argyll-Robertson pupil. He did not use this term, nor did he describe the procedures he adopted in testing the pupil. No other symptoms of locomotor ataxia were described. The Argyll-Robertson pupil is reflex iridoplegia associated with preserved accommodative mobility, that is, where the pupil is as immovable as a frozen opening, no matter how brightly illuminated or how deeply shaded, but contracts when the finger is approached to the nose. It is found early in locomotor ataxia, but it is also found in paretic dementia, and, as might be expected, in constitutional syphilis. It has even been claimed that it is a diagnostic mark of this last condition. Cases of constitutional syphilis, however, occur quite frequently in which reflex iridoplegia is absent. The position taken by Spitzka, fourteen years ago, that this condition is rarely found in constitutional syphilis, can not now be maintained. A temporary iridoplegia has been noted after railroad accidents and other shocks. Exceptionally, the same pupillary condition has occurred in alcoholism and after diphtheria in the adult. For forensic diagnostic purposes this pupil is not pathognomonic of locomotor ataxia. In the case in which the question was raised, the patient had died before trial. The jury gave less than one-tenth of the statutory limit. If the litigant really had locomotor ataxia, this condition, in Dr. Kiernan's opinion, had preceded the accident and was in all probability then contributory thereto. The man had driven a United States mail wagon on the tracks in front of a street-car. Locomotor ataxia under such conditions could prevent him turning in time.

Dr. Casey A. Wood was of opinion that due care was not always exercised by general practitioners, forensic physicians, or even ophthalmologists in the diagnosis of the Argyll-Robertson pupil. There were so many conditions in which similar states occurred that the diagnosis of locomotor ataxia on this symptom alone was not justified.

Dr. William L. Baum could not agree with certain syphilographers as to the pathognomonic diagnostic value of the Argyll-Robertson pupil in constitutional syphilis. In his experience it was too frequently absent to be regarded as pathognomonic of constitutional syphilis. The fact that it occurred in para-syphiloses, like locomotor ataxia and paretic dementia, did not necessarily demonstrate its value as a symptom of constitutional syphilis.

Dr. Kiernan, in closing, agreed with both Dr. Wood and Dr. Baum, that the pathognomonic value of the Argyll-Robertson pupil in constitutional disease was doubtful.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of Bronchitis.

Just at this time of year the physician comes in contact with a great number of patients complaining of colds in the head and bronchial catarrh. In the larger cities this is due in a great many instances to the steam-heated apartments. People emerging from a warmer atmosphere are exposed to the cold air and the body becomes chilled, the circulation of the skin is greatly disturbed and the bronchial mucous membrane congested. Those patients suffering from organic heart lesions—especially where mitral lesions are present, producing a congested condition of the pulmonary circuit—are more susceptible to the changes in the atmosphere and the weather. Such conditions in the extremes of life make the prognosis in attack of bronchitis more unfavorable. The treatment must be directed to the different phases of the disease and to the special symptoms which may arise in each individual case. In this connection we wish to emphasize one point in the management of such cases, just as in all cases of infection, and that is—watch the elimination. Elimination should be promoted, not alone by the kidneys but also by the skin, bowels and respiratory tract. In this way the catarrhal turgescence of the mucous membrane is lessened and the process of free secretion is established. The patient should be cautiously and well fed with most digestible food, having warm clothing for the body and proper protection for the chest. In the milder forms of acute bronchitis the following is of service as an expectorant:

℞.	Ammon. carb.	℥iss	6
	Ammon. bromidi	℥ii	8
	Vini ipecacuanhæ	℥iv	16
	Aq. menthæ piperitæ q. s. ad	℥iii	96

M. Sig.: One teaspoonful every four hours in water; or:

℞.	Ammon. chloridi		
	Sodii salicylatis, āā	℥ii	8
	Tinct. hyoscyami	℥v	20
	Mist. glycyrrhizæ co. q. s. ad	℥iii	96

M. Sig.: One teaspoonful every four hours.

If the patient is strong and of a well-marked sthenic type, according to Sir T. Granger Stewart, antimony is a drug of great efficacy, as follows:

℞.	Vini antimonialis		
	Vini ipecacuanhæ, āā	℥iii	12
	Spts. chloroformi	℥iss	48
	Liq. ammon. citratis q. s. ad	℥vi	192

M. Sig.: One tablespoonful in water every six hours; or:

℞.	Vini antimonialis	℥ii	8
	Spts. etheris nitrosi	℥ss	12
	Liq. ammon. acetatis q. s. ad	℥vi	42

M. Sig.: One tablespoonful in water every six hours. Discontinue when there are symptoms of depression or when free expectoration is established.

In patients presenting signs of feebleness or general weakness, expectorants must be combined with cardiac stimulants, as follows:

℞.	Ammon. carb.	gr. xl	2	66
	Spts. ammon. arom.	℥vi	24	
	Aq. chloroformi q. s. ad	℥iv	128	

M. Sig.: One tablespoonful every five or six hours; or:

℞.	Tinct. strophanthi	m. xl	2	66
	Spts. ammon. arom.	℥vi	24	
	Aq. chloroformi q. s. ad	℥iv	128	

M. Sig.: One tablespoonful every six hours.

When the cough is dry and very troublesome at night, so that the patient is unable to sleep, the following containing codein is valuable, which should, however, never be given so long as the cough brings up phlegm, but to quiet an aggravating cough, is useful.

℞.	Ammon. carb.	3ss	2
	Codeinæ	gr. iv	25
	Tinct. hyoscyami	ʒi	32
	Syr. pruni virg.	ʒiss	48
	Aq. camphoræ q. s. ad	ʒiv	128

M. Sig.: One dessertspoonful every two or three hours.

The free use of expectorants is of advantage in getting rid of particles of dust and foreign substance, which have lodged upon the mucous membrane and act as irritants to the respiratory passages. But we wish to suggest care in the use of anodynes as in the foregoing prescriptions, for too free use of opiates and anodynes impair digestion, produce anorexia, cause constipation and quiet the cough, through which nature is attempting to remove causative factors.

Organic heart lesions, such as mitral regurgitation or obstructive lesions, producing marked congestion and distension of the bronchial vessels, cause a cough and sometimes an acute inflammation. In these cases measures must be taken to support and remove the load by proper cardiac stimulation and free elimination. The patient should be put to bed, so as to reduce the work of the heart, and the following is recommended in such conditions:

℞.	Ammon. carb.	gr. xl	2 66
	Infusi digitalis q. s. ad	ʒiv	128

M. Sig.: One tablespoonful in water every five or six hours.

Acting as indirect heart stimulants by dilating the peripheral blood vessels and thus relieving the pulmonary congestion and at the same time promoting diuresis, the nitrites are valuable:

℞.	Spts. glonoini (1 per cent.)	m. vi	36
	Spts. etheris nitrosi	ʒiss	6
	Spts. chloroformi	m. vi	36
	Alcoholis	ʒi	4
	Aquæ q. s. ad	ʒiii	96

M. Sig.: One tablespoonful every four hours.

Cases of bronchitis, with a history of rheumatism, are best treated by the use of the salicylates in some form, combined, perhaps, with alkalies, as follows:

℞.	Sodii salicylatis		
	Sodii bicarb., āā	ʒii	8
	Syr. glycyrrhizæ co.	ʒss	2
	Aq. foeniculi q. s. ad	ʒiv	128

M. Sig.: One tablespoonful in water every four hours.

And in gouty bronchitis colchicum is very valuable, if a proper preparation of this drug can be obtained. But as is the case in a few other drugs the value of this drug is uncertain, because of the unreliability of the crude drug used in making the medicinal preparation. The following combination is advised:

℞.	Vini colchici (sem.)		
	Vini antimonialis, āā	ʒiiss-iv	10-16
	Pot. bicarb.	ʒss	16
	Aq. gaultheriæ q. s. ad	ʒvi	192

M. Sig.: One tablespoonful four times a day in water.

CHRONIC BRONCHITIS.

The chronic forms of bronchitis require special attention in their treatment, because the degree of activity is not so great as in the acute, but the condition may go on for months or years, being kept up by constant irritation from some source, and this should be sought for and removed if possible. Even greater care must be observed in the clothing, the occupation, the food and the climate. However, in no disease, as Loomis states, is a careful study of each individual case more important. This form of bronchitis occurs in connection with emphysema and diseases of the heart and kidneys in elderly people, and, under such circumstances, the particular cause should be discovered and treated in each case.

Potassium iodid is very often used to good advantage, and has been found very efficient in the majority of cases. The following formula is recommended:

℞.	Potassii iodidi	ʒii	8
	Syr. picis liq.	ʒiii	12
	Syr. acidi hydriodici	ʒv	20
	Syr. tolutani q. s. ad	ʒiii	96

M. Sig.: One teaspoonful four times a day in water.

The aromatic balsams, combined with a mild anodyne, are serviceable if the cough becomes troublesome:

℞.	Balsami copaibæ		
	Pulv. camphoræ, āā	3i	
	Pulv. acaciæ, q. s.		

M. Ft. capsulæ No. xv. Sig.: One capsule four times a day; or:

℞.	Copaibæ	ʒii	8
	Spts. chloroformi	ʒss	2
	Mucilag. acaciæ	ʒvi	24
	Aq. camphoræ q. s. ad	ʒvi	128

M. Ft. mistura. Sig.: Two tablespoonfuls three times daily.

Turpentine is sometimes very efficacious, and it may be given in capsule or in the form of an emulsion according to Yeo:

℞.	Olei terebinthinæ	ʒii	8
	Mucilag. acaciæ	ʒi	32
	Mist. amygdalæ q. s. ad	ʒvi	192

M. Ft. mistura. Sig.: Two tablespoonfuls at each dose, every six hours.

Creosote is a valuable preparation in chronic bronchitis, and may be given in capsules or in the liquid form as follows:

℞.	Creosoti	ʒss	2
	Aq. chloroformi q. s. ad	ʒii	64

M. Sig.: One teaspoonful four times daily.

As a good stimulating expectorant in cases of chronic bronchial catarrh with profuse, stringy, adhesive mucus, such as is often met with in the aged, the following is recommended by Yeo:

℞.	Ammon. carbonatis		
	Sodii bicarb., āā	gr. xl	2 66
	Tinct. camph. comp.	ʒiv	16
	Spts. chloroformi	ʒiss	6
	Infusi senegæ q. s. ad	ʒviii	192

M. Ft. mistura. Sig.: Two tablespoonfuls every five or six hours, administered in hot water.

Medicolegal.

Period of Gestation.—The Supreme Court of Nebraska says, in the case of Erickson vs. Schmill, that, while there is no absolute rule upon the subject, by general consent, based on extended observation, the usual period of gestation is considered to be about 280 days. This is common knowledge, which courts may be assumed to possess. But that the possible period of embryonic existence is more than 300 days is a fact which courts are not bound to know and act on in the trial of causes. That is to say, courts do not take judicial notice of the fact that the possible period of gestation exceeds ten calendar months.

By Whom Existence of Blood May Be Proved.—It is not necessary, the Supreme Court of Idaho holds, in the murder case of State vs. Rice, that an expert witness, or one skilled in chemistry, be called to prove the existence of blood. The experience of man "from the cradle to the grave" so familiarizes him with the appearance of blood that every witness possessing the full use of his senses, who is competent to testify to other matters, is competent to testify to the existence of blood, or presence of blood stains. It is only where there is doubt as to whether the blood is that of a human being or that

of some inferior animal that the aid of chemistry or expert witnesses is necessary.

Physician Calling Wife as Witness to Contract.—The statutes of the State of Washington provide that in an action or proceeding where the adverse party sues or defends as executor, administrator or legal representative of any deceased person, a party in interest or to the record shall not be admitted to testify in his own behalf as to any transaction had by him with, or any statement made to him by, any such deceased person. The case of Whitney vs. Priest was an action by a physician against an administrator for compensation for professional services rendered to the decedent, the wife of the administrator, during her last illness. At the trial, the physician's wife was permitted to testify that she was present with her husband, and that he and the decedent agreed upon the terms of the contract for his surgical treatment of her. This was objected to, as being inhibited by the statute, and the Supreme Court of the State of Washington holds that it was error on account of which the judgment obtained for services must be reversed. It says that the plaintiff and the witness were, as before stated, husband and wife. The professional services which were the subject of contract between the plaintiff and the deceased involved the community interest. The compensation for such services belonged to the community. The physician's wife was interested equally with her husband. She was equally interested in the result of this action. She must necessarily be said, therefore, to be a party in interest. and the transaction and the statements made to the plaintiff physician must equally involve his wife. Hence, the witness fell within the disability of the above provision of the statute, and it was error to admit her testimony as to the transaction and statements made by the deceased to the plaintiff.

Skill Required; Consultation; Diagnosis; Harshness.—The Appellate Court of Illinois, First District, in the malpractice case of McKee vs. Allen, holds that a difference of judgment among medical men as to the best course and method of treatment does not by any means tend to prove that either party is wholly wrong or wholly right. A physician who has given a patient the benefit of his best judgment is not liable for negligence even if his judgment is erroneous, unless the error is so gross as to be inconsistent with reasonable and ordinary skill and care. Again, the court holds that it is the duty of physicians and surgeons to exercise reasonable and ordinary care, skill and diligence in the practice of their profession. To this extent they are liable and no further. They are not required to possess the highest, but reasonable skill. The burden of proof is upon the plaintiff in an action for malpractice to show the want of such care, skill and diligence, and also to show that the injury complained of resulted from failure to exercise these requisites. It can not be said as a matter of law, where a physician recommends a method of treatment recognized and approved by the standard authorities upon medicine and surgery as appropriate to the case in hand, and consults another physician or surgeon who has had experience in the use of such method, and who, after examination of the patient, concurs in his judgment, and the patient submits to the treatment upon such advice, that he has failed to exercise ordinary care, skill or diligence in making such recommendation. If he has not so failed he is not liable. The physician or surgeon is not an insurer of a successful result. Furthermore, the court holds, in this case, that if the diagnosis in question be considered erroneous in calling the disease, which was sciatic rheumatism, chronic, instead of acute, it must still appear that his error in judgment in this respect was not consistent with reasonable and ordinary skill and care; and it must further appear that surgical treatment of acute sciatica was so clearly unwarranted, and such a violation of sound rules of professional practice, as to be also inconsistent with ordinary and reasonable medical skill and care. Then, there was some evidence in this case tending to show that the physician, in the effort to manipulate and straighten the patient's leg, several times resorted to what in her sensitive condition was very painful treatment. But it was apparent that it was employed as a curative measure, and it was not shown to have been injurious. This being all that the court has to say about it is that if his methods in this respect were harsh, the patient was not obliged to retain him in attendance, but was at liberty to employ other medical aid.

155 Report of Surgical Operations in the Private Surgical Infirmary of Drs. C. S. and Samuel S. Briggs During Its Tenth Season, from Sept. 10, 1900, to Aug. 1, 1901. (Concluded.) Samuel S. Briggs.

AMERICAN.

1. **Spinal Myeloma.**—After reporting a case operated upon by resection of the first four dorsal laminæ and removal of the growth, with microscopic examination of the same, Thomas goes at length into the literature of the subject. The specially interesting feature in his case was the very complete relief of the paraplegia by the operation, the presence also of disassociation of the sensations of temperature, pain and touch such as in syringomyelia in a case of pressure upon the cord from without, as well as the variability in the height of the disturbance of sensation as seen at different examinations and the apparent improvement in the condition of the bones under the use of bone marrow and Coley's toxin treatment. The patient recovered enough to go out and tend to his business, but within a few months he had a return of the pain and swelling in the region of the 6th, 7th and 11th ribs, tenderness to pressure, with rigid spine and difficulty in moving. The further progress of the case is not reported. The reflexes were normal.

4. **Infantile Scurvy.**—Two cases of this condition are briefly reported by Pierson, who uses them as a text for his discussion of the disease. The etiology is doubtful. The most that can be said is that it follows the prolonged use of some unsuitable diet. It generally occurs in children under 2 years, usually from 6 to 15 months of age, and as far as the pathology is concerned from the general practitioner's standpoint, it is simply a hemorrhage with which we have to deal. The earliest and most common symptoms are swelling of the lower end of the diaphysis of the femur; that is an important point in the diagnosis from rhachitis or rheumatism. The swelling is neither hot nor red, as in rheumatism. The diaphysis is tender, which is not the case in rhachitis. The rest of the pathology of the disease consists in anemia, which is probably secondary, due to hemorrhage, and ulcerative stomatitis. Swelling of the gums is not usual in his experience and will not appear with prompt treatment. Hemorrhage may occur from bowels, nose, into the skin or into any of the internal organs. The first symptom noticed in the child is pain, terror of being touched, pain first in the legs, then the arms and back; next swellings appear, but there is no fever. The diagnosis should be easy, the most common error is to call the case rheumatism or to attribute it to a fall or injury. In rhachitis the swelling is epiphyseal, chronic and painless, and there will be a well-marked rosary when it is well developed as in scurvy. Stomatitis and hemorrhages do not occur in rhachitis. Pott's disease is rare under 2 years, and has no swelling of the extremities. Acute anterior poliomyelitis has a febrile onset with later paralysis. Purpura has no swelling of the extremities or stomatitis. Syphilis is more chronic and the swellings less tender. When anyone is called to a child lying with legs drawn up, dreading to be touched, with swelling of the lower end of the diaphyses of the long bones and where there is anemia, with swollen gums, there is no other diagnosis possible than scorbutus. The treatment is simple. Modified, uncooked milk with orange or lemon juice should be given, one-half to one lemon or orange being used daily with fresh beef juice. He usually gives iron, etc., for the debility and anemia. In severe cases the child must be kept quiet on a frame, but he has not had to resort to this.

6.—See abstract in The Journal of October 5, p. 933.

7. **Teaching of Anatomy of the Nervous System.**—Mettler criticises the former methods of teaching nervous anatomy and suggests biologic methods, showing the evolution of the organs from the lower types and uses the spinal cord as an illustration. He shows how this is evolved from the ganglion system of the invertebrate, and that certain portions recognized as belonging to it, are so only by grace of position, but really are parts of the cerebral anatomy. The importance of putting the function and development of the parts before their mere anatomic location enables the student to grasp more intelligently the relations and conditions than would otherwise be the case.

8. **Pre-Medical Education.**—Coulter describes the pre-medical course adopted in Purdue University, which was devised to furnish a broad and liberal education and give special and extensive training in subjects which underlie primary professional studies, and, by this co-relation of work, to shorten the time required to obtain a university and medical education. The needs of the student beginning a medical course are considered, but he thinks if the professional school and college can make satisfactory allotment of courses common to both, that time, money and strength would be saved.

9.—See abstract in The Journal of July 13, p. 138.

10. **Pistol-Shot Wounds.**—The characteristics of wounds from pistol bullets are described by Curtin, who speaks of the importance of knowing the distance at which the pistol was held from the victim, which can be most accurately determined in most instances. When the pistol is held tightly against the skin, the entrance wound is large as compared to the caliber of the pistol, the edges of the wound are burned and lacerated and there is no surrounding area of blackening, burning or powder stain. If only one or two inches away, the wound is small, but there is a blackened and scorched area around it and the hair is burned. The farther away the pistol is held, up to a certain limit, the more distinct are the imbedded powder stains. The burning of the skin is present up to a range of six inches; it is variable, however, from three to six inches. The presence of powder grains shows that the range has not exceeded five feet, while smoke stains are constant up to a distance of eight inches. If the pistol has been held at some distance, say ten or twenty feet, the entrance wound is small or rounded. There is no blackening around it or any mark of powder stain. The caliber, the length of the barrel, the amount of powder used and its age are all to be considered. In head cases there is very little bleeding at the entrance wound; oozing of brain matter is present in 50 per cent., but both these may be lacking. One should notice the shape of the entrance wound, whether it is distinctly rounded or whether tunneled or grooved. This is important as determining the relative position of the parties. The entrance wound is smaller than the caliber of the bullet, except when the pistol has been fired in direct contact. This is due to the elasticity of the skin. He has rarely seen an exit wound of pistol-shot wounds

of the head. A 22-caliber bullet fractures the skull, it may or may not lacerate the meninges, and rarely enters the cranial cavity. The 32-caliber penetrates the brain, and if it passes through the squamous portion of the temporal bone, it usually produces a comminuted fracture of the bone opposite. It can be best detected by careful external palpation, and sometimes the extraction of the bullet and bone fragments are effected. The bullets of from 38 to 42-caliber penetrate, and in some cases perforate. Accurate anatomic description of the wound of entrance and exit should be made. It is important in giving legal testimony to know the caliber of the bullet. This is determined by accurately weighing the leaden mass and comparing it with standard weights of the different calibers. The caliber sought for will be that one which corresponds with the weight, exceeding by a few grains the weight of the leaden mass. The pistol should always be examined to see if it had recently been discharged. If so the barrel is lined with a black deposit of sulphid of potassium and charcoal, which, when diluted with water, gives a strong alkaline reaction, has the odor of sulphureted hydrogen and a deep brown precipitate forms on the addition of acetate of lead. If the pistol has not been fired for hours or days, this black precipitate changes from the sulphid to the sulphate of potassium, which gives a neutral reaction in a watery solution, and a white precipitate on the addition of acetate of lead. If the time which has elapsed amounts to weeks or months, traces of the oxid of iron as well as of the sulphate of iron will be found. He calls attention to the wounds made by blank cartilages and it is well to remember that they have been known to penetrate to the depth of two inches. From their action in carrying germs and the frequency of tetanus, attention to their removal and treatment of the wound is imperative.

11. **Strangulated Hernia.**—The condition of strangulated hernia, as considered by Pfister, is entirely within the scope of those conditions which the general practitioner can treat, and no more than a fair modern surgical education is required. No rarely-used instruments are needed, and it is so frequent that every physician should inform himself on the technique of the operation, and, with the simple procedures, have successful results in the vast majority of cases. He goes at length into the description of the operation and says in conclusion that there are many conditions, such as advanced age, where a well-adapted truss will suffice, and therefore not all cases of hernia, aside from severe strangulation, should be operated upon.

12. **Tuberculosis.**—The details of the sanatorium treatment of tuberculosis are given by Richer, who lays stress on the importance of rest, including under this term not only the recumbent position, but quiet and the use of bandages to insure long rest to any injured parts, outdoor life, over-feeding, of which he gives the details, and general medical supervision. This last is the most important. He finds that strychnia in 1/30 gr. doses is very useful and creosote is the most reliable internal antiseptic, except where contraindicated by recent hemoptysis. Cough is easily controlled and night sweats disappear with increased nutrition.

16. **Epilepsy and Dyspepsia.**—The close relation between epilepsy and dyspepsia are insisted upon by Aaron, who believes that gastro-intestinal irritation seems to be the cause to which many cases of epilepsy are traceable. The digestive troubles are frequently latent. It is to be recommended in all cases of epilepsy and suspected stomach disorders, that an analysis of the stomach contents and urine should be made. The examination of the patient is not complete unless the digestive organs are also examined.

17. **Social Aspects of Dermatology.**—The subjects considered in Morris' fourth lecture are the pus bacteria of the skin with their consequences, impetigo contagiosa, boils, carbuncles, etc.; anthrax, sycosis, premature grayness, alopecia, acne, vaccination rashes, and tropical parasites; chigos, guinea worm, elephantiasis, etc. Morris believes in the hygiene of the barber shop. He points out that nearly all hair dyes are injurious.

19. **Climate in Nervous Diseases.**—Pearce finds that neurasthenia, chorea and other diseases are badly affected by high altitudes and high winds. He thinks therapeutic climatic results are dependent upon the states of atmospheric pressure and consequent nutritional modifications. High altitudes favor circulation in the periphery and assist nutrition; the trophic functions may advance too rapidly with too great ascents. The neurasthenic, therefore, who must appropriate nutriment slowly on account of the weakened central nervous system, is not suited to high altitudes. Insomnia is benefited by lower altitudes, as are also chorea, hysteria and most of the functional diseases. Melancholia and depression are helped by high winds with moderate heat to aid in general bodily metabolism. The organic diseases dependent on the central or peripheral lesions, perverted function, as pain and sluggish circulation, will be helped by altitude. A greater altitude is desirable for diseases of the central nervous system, and a lesser altitude the desideratum in the cases of peripheral diseases, as in neuritis and vasomotor palsies, exophthalmic goiter, etc.

21. **Acute Amygdalitis.**—The conclusions of Floersheim's article are: 1. The tincture of iodin is the most powerful antiphlogistic in inflammations of the throat. 2. Its action is very rapid, relief being often experienced within five minutes. 3. It has relieved the intense inflammation completely when all other throat remedies had absolutely failed to benefit. 4. Its use in sixty-eight cases of acute amygdalitis has been followed by marked benefit in every case. 5. The method of application is simple.

23. **Cancer of the Gall-Bladder.**—According to Manton very little advance has been made in our ability to distinguish the morbid conditions in gall-bladder and bile duct. Cancer of the gall-bladder is not nearly so uncommon as generally supposed, and in many cases where adjoining organs have become secondarily affected, the secondary growth has been credited as primary. The etiology is the most important question, however, and we know at present but one incontestable factor, viz., gallstones, hence the value of early treatment of this condition. Manton reports a case of villous cancer of the gall-bladder with secondary invasion of the adjoining structures, which was operated upon, but died shortly after the operation. The interesting points of the case are the long-continued gastric disorder and secondary infection long before symptoms pointing to the original condition were developed, the sudden appearance of the gall-bladder tumor and the extraordinary size of the stones. When we consider the frequency of gallstones and the fact that they may be promotive of malignancy, their importance must not be overlooked. He also reports a case of cancer of the common bile duct and secondary infection of the common gall-bladder, illustrating the peculiarities of the case. His conclusions are: Although primary cancer of the gall-bladder and bile ducts is rare, recent investigations go to show that it is not so uncommon as generally supposed. As a rule, the onset of the condition is insidious; there are no symptoms developed at an early stage of the disease in either locality, with which we are at present acquainted, which will permit of a positive diagnosis being made. When this is possible the disease has already advanced beyond the helpful intervention of surgery. Fever, having been observed in so many other conditions of the liver and adjacent organs, it is of little or no value as an aid to diagnosis. This same may be said of blood examination. Emaciation is frequently absent, and the patient may remain in apparently good health until toward the termination of the disease. The absence of malignant disease elsewhere has no diagnostic significance. The only symptom which may perhaps prove of service in forming a provisional diagnosis of gall-bladder and bile duct malignancy seems to be of gastric origin. In two of the cases reported, and in many cases found recorded in the literature of the subject, disorder of the stomach preceded the local symptoms of cancer. Further investigation along this line is desirable, and all protracted disorders of the stomach which can not be positively referred to other causes should be

viewed with suspicion as a possible indication of beginning malignance in the gall-bladder or bile ducts.

24.—See abstract in The Journal, xxxvi, p. 1416.

25. **Cleft Palate.**—The importance of the palate rather than the tongue in the production of speech is insisted upon by Makuen, who shows that the function of the former is twofold, and in all voice sounds in which it does not share in the formation of the stop position, it serves as an obturator between the nose and the pharynx, completing the partition between these two cavities, and compelling the outgoing breath to pass through the required particular stop position required for sound. Thus in labials, labiodentals and linguodentals, the sounding breath must pass through the anterior stop position—that is the place where the anterior stop position is made by impeding the moving column of breath in producing the sound; the middle stop position is used in certain articulations and the sound breath must pass through this constricted aperture. The function of the palate is to prevent its passing upward through the nostrils. In the use of the posterior stop position, which is formed by the junction of the velum palati and the dorsum of the tongue, the soft palate serves a double purpose. Its free border rises against the posterior pharyngeal wall, closing the avenue to the nostrils, and its anterior surface, acting in conjunction with the tongue, forms the stop position for the sound. The palate may be defective by perforation of the cleft or paralysis of the muscle. Perforation must be posterior to the stop position in use, to affect speech, though its importance largely depends upon the size. The characteristic speech of cleft palate is well known and the physiology is explainable by the points already elucidated in regard to stop positions. He calls attention to the importance of treating defects of speech early, and if cleft palate is only operated upon after the speech has been acquired the habit will be retained to a greater or less extent, hence the importance of training and education in such cases.

27. **Yellow Fever.**—Waldauer reports experiences which point out to him the probability of transmission of yellow fever by fomites, and, therefore, insists on the importance of continuing the precautions that have formerly been used as regards the transmission of this disease.

30. **Anesthesia and Analgesia.**—The different actions of general anesthetics are here discussed. Local anesthesia is passed by as being rather analgesic than anesthetic. What we understand by anesthesia is producing general intoxication of the body and suspension of consciousness, leaving untouched the vital reflexes of organic life. It is rapid in induction and recovery, and affecting to the least possible degree the tissue, life and function outside of the desired period of suspended sensibility. Search is never ending for the best means of producing such conditions. Magill goes into the physiology of anesthetics to some extent, showing that toxic action increases in the direct ratio to concentration of carbon in the radical of the agent, as does also the rapidity with which anesthesia can be induced. The addition of oxygen to the hydrocarbon molecule probably renders the anesthesia no more toxic, but slower to be induced. The compound formed by a halogen with the organic radical shows greatly increased toxicity, and this toxic factor multiplies directly with the number of elements of the halogen introduced into the molecule, and likewise directly with the relative density or weight of the halogen in question. By reason of the hyperchlorination of its molecule, chloroform is justly proclaimed more toxic than its rival, but an offset compensation is constituted by its correspondingly increased anesthetic energy. The substitution of bromin instead of chlorin in equal numbers of atoms, determines a greater toxicity for the resultant bromid. The halogens of greater atomic weight should increase the toxicity of the molecule so as to render them dangerous in even the minutest doses. The use, however, of monobromid of ethyl is harmless for short administration, but must not be continued; the author gives particular points in regard to the use of this drug. He finds that there is a growing consensus of belief that if chloroform could be relieved from the accidents of primary syncope it would be the best anesthetic. To avoid the point of danger, the cerebral cortex excitement, the English surgeons are employing nitrous oxid to induce the anesthesia. Drs. Hartman and Bourbon and the writer suggested ethyl bromid, and have extensively used this remarkable agent of short narcosis since 1892. The advantages of this method of beginning the anesthesia with ethyl bromid and continuing with chloroform are insisted upon, the importance of perfectly pure ethyl bromid being specially emphasized. For prolongation of unconsciousness, the narcosis induced by this bromid is easily and safely continued with chloroform in very small quantities.

33. **Adrenal Solution.**—Cohen reports a case in which the use of adrenal extract given for asthma seemed to cause excessive edema of the uvula and palate and adjoining regions, inducing also slight edema of the epiglottis. The patient had sprayed the pharynx and nasopharynx vigorously for a prolonged period with suprarenal-chloretone solution. The uvula and palate were scarified, the patient was put at rest, had a drastic purge given, and was advised to use a gargle with lukewarm water aromatized with toilet vinegar. In about an hour the edema began to subside, breathing became easier, and still later the patient became quite comfortable. Traces of edema of the uvula were visible for three or four days. The preparation used was not the one now usually available, but the extract of suprarenal substance with chloretone, which was previously placed upon the market. He has used the adrenal chlorid solution as now prepared with much satisfaction and without any ill effects.

35.—See abstract in The Journal of October 12, ¶59, p. 1005.

36.—See abstract in The Journal of September 28, p. 850.

50. **Thrombosis of Central Artery of Retina.**—From a study of a case and the literature, Welt finds that the ophthalmoscopic picture of so-called embolism of the central artery of the retina may be produced by thrombosis of the artery, and that this may take place from the following: 1, endoarteritic changes as in von Michel's case; 2, as a symptom of thrombosis of an entire arterial tract as in Siegrist's case; 3, independently of endarteritic changes, when the blood pressure is reduced and there is a tendency to coagulation of the blood and fatty degeneration of the intima, as in his own case.

51. **Embolism of the Central Artery of the Retina.**—Schweigger questions the frequency of embolism of the central artery, doubt as to which was expressed by him more than thirty years ago, but only in recent years has the anatomic basis been given for these cases of sudden blindness by the demonstration of endarteritis with narrowing of the lumen, which accompanies various forms of retinal diseases. The view that sudden blindness with cloudiness of the disc and retina depends upon embolism arose only because the appearance that was previously termed infiltration, later was termed embolism. Graefe's case teaches that embolism is not immediately followed by cloudiness. On the contrary, the narrowing of the retinal arteries from endarteritis must needs cause slowing of the blood count, which may produce infiltration. This peculiar cloudiness of the retina may develop without circulatory disturbance, as he shows by a case of his own, which he thinks was probably caused by a shot striking the optic nerve.

52. **Bell's Phenomenon.**—This phenomenon, discovered by Sir Charles Bell in 1823, consists in associated movement of the eyeball, cornea turning up and in and then up and out, where it remains while the lids are held closed. It is not a pathologic phenomenon, though it was originally held as such from experience in cases of facial paralysis. The cause of it has not been fully cleared up. Nagel has investigated the matter himself and gives the opinion that the phenomenon is really a normal reflex. Whether we must not concede a simultaneous innervation of the orbicularis and the elevators of the eye dependent upon cortical associations, as has been assumed by Mendel and Negro, is not definitely decided. He thinks it is not impossible that Bell's movement in ordinary closure of the

lids is a reflex, depending upon the closure, but in spasmodically intentional closure of the lids the excitation may reach some higher point of the central nervous system, possibly the cortex.

60. **Uterine Fibroids.**—Noble gives an analysis of 218 cases of fibroids tabulating their complications, which are numerous; some of them fatal, some threatening the life of the patient and some leading to permanent invalidism. He has not seen any similar tables of complications to offer a basis of comparison, therefore he is not sure whether his experience is the same as that of others. Accounts are given of some notable cases; his experience does not support the doctrine that fibroids disappear with the menopause, and he thinks this is not to be expected. In the tables no mention is made of adhesions which were present in numerous cases. The most characteristic symptom of patients suffering from these tumors is anemia, which in some exists in the highest degree. In one case in which hysterectomy was performed the anemia was high—hemoglobin 10 per cent. and red cells 2,325,000. The results were favorable, and, comparing the mortality of fibroids and complications—33 per cent.—with the mortality of the operation—with less than 10 per cent.—he thinks the results very much in favor of operation. The proper treatment of fibroid tumors is their early removal; there may be exceptions to the rule, and each case must be decided upon its own merits. According to his own experience, small multinodular, subperitoneal fibroids in women over 40 are less apt to grow and cause trouble; submucous, and intramural growths in younger women are more apt to develop and need operation. He has met with but few fibroids that do not produce symptoms. Therefore he thinks the percentage of cases is small in which operation is not indicated.

61. **Ureterocystotomy.**—Smith has experimented with the lesions of the urinary bladder and the ureters under tension as would be the case from the resection of a ureter with a loss of length. He has experimented on the cadaver and living dogs. The oblique operation referred to below is as follows: "An incision of an inch long is made, in an antero-posterior direction, through the bladder peritoneum; this is dissected to each side, exposing the underlying musculosa. At the distal end an opening of sufficient size to receive the ureter is made into the bladder. A fine silk ligature is now passed through the muscular wall of the bladder, from one-quarter to three-eighths of an inch above the opening; this also grasps the ureteral wall, penetrating the lumen, at such a distance from the end of the ureter as to permit it later to enter the bladder. Before tying this a second suture is passed in a similar manner just above the bladder opening. After these are tied the end of the ureter is inserted into the bladder, and two additional sutures are applied in a like manner at the edge of the bladder opening, firmly grasping the bladder wall and penetrating the ureteral lumen. The reflected peritoneum is now drawn over the ureter by interrupted silk sutures, placing the ureteral sutures extraperitoneal." The conclusions which he reaches are as follows: "1. It is practicable to anastomose the ureter to the bladder under tension, if the two are securely held in apposition till firm adhesions form. 2. This relation can be attained by the above-described method of oblique implantation. 3. An additional length of one-half to one inch can be safely obtained by traction on the ureter. 4. The presence of a ligature in the lumen of the ureter is not injurious, because Nature conceals it behind new epithelium."

62. **Conservation of Ovaries.**—Beyea reports a case in which conservative operation was performed, leaving the lower portion of the uterus, perhaps 1 or 2 centimeters, in the patient, who had been suffering from large myoma; he also notices other cases in the literature. He suggested the following questions as regards the practicability of this conservative hysteromyomectomy: 1. Of what value are ovulation and menstruation when the possibility of conception is destroyed? He believes that this function of the ovaries is a very important matter whether the uterus exists or not. 2. In what frequency will pathologic changes develop if the ovaries are left in position? He has not seen much to indicate their probability and considers they will be extremely rare. Secondary atrophic changes may take place, but he thinks will probably not occur. In the four cases reported by Abel there was a gradual atrophy or diminution in size, but there were no symptoms of menopause, and the molimina menstrualia were normal. There is, he thinks, no sufficient technical reason why the operation should not be performed nor any cause why it will be more dangerous than an early hysteromyomectomy.

75. **Uterine Hydatids.**—A case of this rare condition is reported by Smith, who defines it as a pathologic condition of the chorion characterized by the existence in the uterine cavity of a large number of translucent vesicles, containing a clear limpid liquid, which closely resembles the liquor amnii. A peculiarity is its proneness to penetrate the uterine walls. The causes are noticed; it begins usually in the multiparæ at the close of the child-bearing period, and is characterized by symptoms indicating the mechanical pressure of the growth, hemorrhage, etc. The prognosis is determined by the frequency and violence of the attending hemorrhage. Immediate evacuation of the uterine contents is always advisable if the diagnosis is established before the appearance of labor.

78. **Cystocele.**—The operation here described by Taulbee is that of dissecting or stripping of the perineum from the bladder by a vaginal operation, packing with gauze, then opening the abdomen and suspending the bladder to the abdominal wall by sutures passing into the muscular tissue but avoiding the mucosa. The difficult feature of the operation consists in the properly divesting the bladder of its peritoneal covering and reapproximation of the same, properly inserting the ligatures and denuding the area which it is desired should adhere to the pelvic or abdominal fascia. Care should be taken to avoid all arteries and veins and not to injure the mucous or submucous layers of the bladder. The ligatures must be so adjusted that tension will be uniform and the denuded surface hold the peritoneum to the abdominal wall. The ureters must not be disturbed. The point of entrance and exit of the needle must conform to the size of the distended bladder, which will vary in different subjects. In another operation which he promises to report in the future the vaginal vault was not opened, the uterus and bladder were suspended through the abdominal opening and drainage carried on through this wound; the result, however, was not so satisfactory. He claims priority in his operation, as he has not found anything in regard to it in the literature.

80. **Infection in Abortion.**—From a review of the literature Porter holds the evidence warrants the following conclusions: "1. That acute infections of the genitalia frequently cause abortion. 2. That many attempts to produce abortion criminally, succeed only because of the infection introduced in the attempt. 3. That habitual abortion is usually the result of chronic infection. 4. That, other reasons aside, examinations of pregnant women should be conducted with careful attention to asepsis for fear of inducing abortion. 5. That aborting women should be regarded by the physician as infected women and that he should as carefully disinfect himself after administering to them as he would after attending cases of puerperal infection, etc., before undertaking other obstetric or surgical cases."

85. **Gastric Ulcer.**—Davis describes the symptoms of gastric ulcer, calling attention to the necessity of examination of the stomach contents, and the recognized need of greater care in studying the urine in these cases, paying attention to the reduced acidity and well-marked alkalinity wave after meals. Also the blood examination; the rare cases where there is a hyperchlorhydria may create difficulties, and, when the tumor can not be felt, a diagnosis may be impossible. He goes into the dietetic and medicinal treatment of these cases, making the rest and milk diet the essentials; a guarded prognosis should always be given. In conclusion he suggests the need of laboratories and the advisability of medical societies organizing and supporting these, so that their advantages can be obtained by the practitioner in general.

87. **Appendicitis.**—Davis ends his paper as follows: "In all cases of chronic appendicitis and those who have had one or more severe attacks, or two or more light attacks, an operation is indicated. 2. In simple cases of appendiceal colic without severe pain, no vomiting, no fever and no rise of pulse rate, immediate operation is not imperative, though the appendix should be removed at the earliest convenience after the attack is over. 3. In acute attacks seen during the first forty-eight hours, accompanied by persistent vomiting, severe pain and rigidity of the right rectus abdominis, immediate operation should be done whether there be much fever or rise of pulse rate or not. 4. In patients seen after the third day of the attack (*a*), if distinctly convalescent, operation may be postponed until the acute symptoms fully subside; (*b*), if not distinctly convalescent, but with an amelioration of all the acute symptoms, immediate operation should be done; the operation may be delayed if the patient can be closely watched and is in suitable surroundings for an immediate operation should there be an exacerbation of the symptoms; (*c*), in patients becoming progressively worse, but not yet moribund or nearly so, operation done at once will save more patients than can be saved by other means; (*d*), moribund patiènts should be allowed to die without operation."

88.—This article appeared in The Journal, xxxvi, p. 1157.

95. **Sulphid of Calcium.**—Earp finds that this is a valuable remedy in scrofulous cases and in the treatment of boils, felons and acne, and is an adjuvant to mercury and iodid of potassium in specific cases. He quotes letters from Dr. H. A. Hare, who endorses the remedy, and thinks it does good where there is a tendency to the development of pustular conditions of the skin; he also quotes from Dr. D. M. R. Culbreth, who speaks highly of it in scrofulous or glandular conditions when used with discretion and judgment. It should not be used too generally. He thinks it a valuable agent in knowing hands. Dr. G. F. Butler has had but little personal experience, but is convinced that it is an efficient remedy in the class of cases in which it has been recommended by Earp.

97.—See abstract in The Journal, xxxvi, p. 1726.

105. **Apex Pneumonia.**—From a study of cases, including the statistics of Pye Smith and others, Cordell concludes that: "Acute lobar pneumonia affecting the apex is about one-third as frequent as that affecting the base, and of the two apices, the right is affected about three times as often as the left. Involvement of one apex and the opposite base is very rare, and that of the two apices still rarer. Apex pneumonia is not rare in early life, and the relative involvement of the upper and lower lobe corresponds with that in the adult. The general mortality of the apex and basal forms is about the same. Involvement of one apex and the other base does not appear to be a fatal form of double pneumonia, apart from complications. The mortality of uncomplicated apical disease in the child is almost nil. Delirium is not an infrequent prognostic symptom at any age. Intemperance and hyperpyrexia do not increase the relative mortality at the apex. Pericarditis is a fatal complication, and Bright's disease and bronchitis render the prognosis much graver. Delirium is not a more frequent or marked symptom in apex cases in the adult, and seems to occur more often in cases with complications than in the basal form. Intemperance, which is the chief cause of this symptom, does not seem to increase its relative frequency at the apex. There is no positive evidence that delirium is more frequent or prominent in the young with apical pneumonia. Pericarditis is relatively more frequent in apex cases. The same appears to be the case with otitis media. It is not evident in the case of icterus, hyperpyrexia, endocarditis, meningitis, pleurisy, diabetes, or empyema. Gangrene is doubtful. There is no reason (other than site) why apex pneumonia in the adult should be more readily overlooked. Phthisis is rare in connection with acute lobar pneumonia, and the apex form involves no tendency to eventuate in it. Cases of apex pneumonia, even in the adult, sometimes assume the mildest symptomatology."

111.—See abstract in The Journal of September 14, p. 711.

118. **Enuresis.**—Barbour recommends the use of boracic acid in enuresis. He was led to employ it from his desire to render the urine less alkaline and more antiseptic. Later he added salol to the boric acid and the results have been most gratifying, so that it has become his routine treatment for enuresis. Abnormally contracted bladder and conditions like malnutrition, etc., can not be thus benefited. He does not give the dosage in which he has employed the drugs in these cases.

119. **Hydrotherapy in Neurasthenia.**—The method here advocated by Sinkler is as follows: The patient is placed in a hot-water cabinet until perspiration begins, then given the circular or so-called needle bath for one minute, beginning with a temperature of 95, gradually reducing it to 85 with pressure of 20 pounds. The Scotch douche is then applied to the spine, alternating hot and cold water, at a temperature of 105 and 80, under the same pressure. The treatment usually first lasts only 25 or 30 seconds. After a few days the pressure is increased to 25 or 30 pounds, and the extremes of temperature used are much greater, alternating from between 110 and 70. After about two weeks' treatment, in addition to the circular and Scotch douche, the fan douche may be used for the body, abdomen and extremities. The patient's condition should be carefully watched, and if reaction is not good, go slowly in reducing the temperature and increasing the pressure. It is his custom to have the pulse, temperature and respiration taken before and after the treatment, and have the patient weighed also before and after. After the bath, brisk friction is applied with a warm, dry towel, and a few minutes' general surface massage is given; then the patient is sent out for a walk. Taking exercise after the bath is a point which Dr. Baruch insists upon as it promotes reaction. Hydrotherapy does not agree with all neurasthenics and each case should be treated individually and carefully watched. But if the different baths produce an unsatisfactory result it is best to begin with the wet pack and sponging of the spine witth warm and cold water at home. In some cases the drip sheet does more good than either the wet pack or hot bath. Insomnia is a condition greatly benefited by this treatment, also melancholia and other conditions.

125. **Gallstones.**—McCalla reports a case in which after cholecystotomy followed by fistula and apparent obstruction of the gall duct from inflammation due to impacted stones which were removed, he waited until after the peritoneal cavity was sufficiently isolated from the drainage wound and used hot water, temperature 130 F., at a pressure of several feet for some seconds to force an opening in the duct, with success. Later he carried the water pressure as high as twelve feet. The result was that the bile escaped into the intestines, the drainage wound healed up, and the patient recovered her health.

130. **Tuberculosis.**—Gibbes says that he would not be surprised if Koch had a still more startling statement yet, and the one in regard to human and bovine tuberculosis was somewhat of a pioneer balloon. It must be remembered that he has never gone so far as some of his disciples, and that years ago he admitted having seen cases where no tubercle bacilli could be found. Gibbes himself believes that there are two conditions which go under the name of consumption and which should have entirely different treatment. The first is purely inflammatory, beginning as a bronchitis, extending into the lungs as bronchial pneumonia and forming a consolidation varying according to the intensity of the inflammation and the number of infected bronchioles. If the vitality of the patient is low or the intensity of the inflammatory process great, so as to overcome the natural resistance of the part, necrosis results, and after a while a cavity is formed. Careful study of these facts has proven that they are purely inflammatory from first to last and bacteriologic examination fails to reveal the tubercle bacilli in sections of any consolidation of the lungs until these organs begin to break down; then they are usually pres-

ent in large numbers. He asks when these cases become tubercular; he feels sure that it is the stage when the tubercle bacilli appeared and that was when the diseased process had destroyed so much lung that the patient would have died anyway. He maintains that over 50 per cent. of lung cavities are due to bronchial pneumonia. The other form is an entirely different process. The patient commences with stooping and rounding of the shoulders, lassitude and fatigue, dulness of the apex, generally the left. There may be no cough at this early stage, the dulness constantly extends downward and then gradually all the familiar symptoms develop. There is no expectoration in the early stages as the bronchi are not affected. There is no acute inflammatory process extending into the lungs, the diseased process is going on in the lung itself and consists of a new growth, which starting in one apex gradually substitutes itself for the normal lung tissue. We have, therefore, two disease processes, differing in everything but their results, viz., cavitation of the lungs, and they must not be treated in the same manner. The difference should be recognized at once on examining the case. The principal perceptible difference appears to be the existence of moist râles between the edge of consolidation and the functionating lung, indicating a positive bronchial pneumonia instead of a tubercular growth of abnormal tissue.

140. **Medico-Sociologic Problems.**—The evils from vices and mistakes in the raising of children are noticed by Kime, who advocates the sterilization of criminals and the prohibition or restriction of marriage of idiots, insane, tuberculous, epileptics, dypsomaniacs and syphilitics, also the raising of the age of consent and the regulation of child labor. These are a few things which he thinks would favorably affect the development of the race; others will be considered later.

143. **Epilepsy.**—Spratling's article considers the subject of epilepsy, particularly its causation, and finds that nearly 85 per cent. of epileptics became so before they reached the age of 20 and that the four factors of heredity—epilepsy, alcoholism, insanity and tuberculosis—in addition to the cerebral palsy cases of early life, produce 67 per cent. of all cases we meet. The time to treat the epileptic, therefore, is while he is young, and the disease but recently developed. As regards surgical work, he thinks much that has been done ought not to have been done. The great principle of doing no harm should be observed in these cases. Before any operation is undertaken to relieve the epilepsy the case should be studied from all sides, taking into account the hereditary factors, character, duration, etc., of the seizures, and especially the mental condition of the patient at the time. If this has been impaired he doubts the propriety of any operation as a means of cure. He does not wish to create the impression that epilepsy is incurable, for some can be cured and fully 75 per cent. of all cases can be greatly benefited.

147. **Tuberculosis and Trades.**—The question as to what business had best be carried on by tuberculous patients is treated of by Ambler, who thinks that tuberculous patients should not have charge of public halls or places where people assemble. He calls attention particularly to clerks and others that handle food stuffs. The butcher, the thinks, generally possesses an immunity, at least that has been his experience, but bakers are particularly susceptible. While the baking of bread may destroy the tubercle bacillus that has gone into the material before, and in this respect diminishes the danger, this is not the case with green vegetables or those that are eaten in the same condition in which they are purchased. Tuberculous individuals, therefore, should not be employed in market places or in stores generally, and yet there are few physicians who can not cite cases where such are employed in just these occupations.

FOREIGN.

British Medical Journal, September 28.

The Action of Arsenic on the Healthy Tissues of the Skin. Leslie Roberts.—The action of arsenic on the skin is, to some extent, veiled in uncertainty. It is astonishing how readily it can gain access to the body, food, garments, wall paper, etc. In fact whenever chemists wish to test its presence in any body they require previously to satisfy themselves that it is absent in the reagents and all apparatus to be employed. Starting from the scientifically established fact that arsenic possesses like hemoglobin a respiratory property, as shown by Binz and others, we must seek the answer to the question, whether the development of active oxygen within the tissues of the skin is actually the direct cause of morbid changes in these tissues and of the whole train of symptoms which accompany arsenical poisoning? In other words, is the cause dynamic rather than simple and direct and are the extraordinary effects which it produces of a nutritive rather than of an inflammatory order? After these introductory remarks Roberts notes the presence of arsenic in the human tissues and shows that the thyroid gland contains by far the largest proportion. It is also found in very small quantities in the mammary glands, thymus, with traces in the hair, horns, skin, milk and bones, with not a trace to be discovered in the blood or urine, and but a very minute one in the feces. Arsenic is, therefore, with one variable exception found in the areas of quiet oxidation, while all those in rapid oxidation are free from all traces of it. Normal physiologic arsenic is also removed from the body chiefly by keratinized cells of the cutaneous epithelium and in very minute quantities by the feces. It seems possible that the health of the body, as well as the maintenance of healthy metabolism of the skin, is dependent upon the chemical partnership of mercury, iodids, phosphorus, and arsenic, largely in the thyroid gland. The effects of arsenic on the skin are, 1, pigmentation; 2, hyperkeratinization; 3, desquamation; 4, atrophy, and 5, fatty degeneration. The pigment is melanin, which appears to be developed within the germinal epithelium as the result of arsenical stimulation. Hyperkeratinization is the most important sign of arsenical poisoning. It involves the strata above the cones and the tendency is toward complete arrest of inward growth. Desquamation is another highly characteristic symptom, especially in its chronic manifestation. Atrophy and fatty degeneration are later phenomena. Gautier infers, and it may be proven possible in the future, that there exist in the body certain functional elements. Only a few of these have as yet been discovered, but he assumes them to be essential for certain specific functions. Thus manganese is said to be essential to the oxidizing ferment; iodin to the thyroid; phosphorus to nucleins; fluorin to the bone cells. Some of these functional elements appear to play the principal part, others may be styled substitution elements; thus arsenic may take the place of phosphorus in relation to nucleins; selenium act for sulphur; copper, zinc or manganese may replace iron and so on. But one thing we have to learn, viz., that arsenic is not merely a drug possessing curative powers, and that it is not necessarily an irritant poison; that it is not a poison in itself, but that its action is initiated and determined by the tissues themselves; that its effects are essentially of a nutritive order brought about by the agency of active oxygen, and that these effects are beneficent to the organism when the oxidation is slow, and injurious when too rapid. The more highly organized the cell and unstable its protoplasm and the more rapid its metabolic processes, the more rapidly does it feel and manifest the action of arsenic.

A Note on the Morbid Conditions Simulating Adenoids. Wyatt Wingrave.—The conditions that simulate adenoids are, according to Wingrave, as follows: 1. Diminutive choanæ and nostrils, which are frequent; usually associated with a low pharyngeal vault and imperfect maxillary development; immobile velum palati, and a gothic arched palate. The nostrils may be uniformly diminutive, or may be normal, while the turbinals are disproportionately large. The former condition seems to be associated with development of the maxilla while the turbinal disproportion is especially associated with puberty and the balance may not be restored for several years. 2. The low pharyngeal vault which occurs in rickety children, and often accompanies the former conditions. 3. Paresis of the soft palate and pharyngeal muscles, which may be the result of any form of nasal obstruction and due to various forms of

paralysis or neglect, or bad breathing habits. 4. Prominent crest of the vomer or backward prolongation of the nasal septum, which is not rare. This is often associated with other abnormalities. 5. Forward projection of the vertebral column, in which the arch of the atlas is the chief offender, though the second and even the third cervical bodies may often be involved. 6. Retropharyngeal abscess, and here Wingrave calls special attention to the retropharyngeal lymphatic gland, supposed to be only present in early life, and which may be the seat of acute or chronic inflammation, giving rise to swellings that seriously encroach upon the upper passages. 7. Undue prominence of the soft parts covering the internal pterygoid plate and the tuberosity of the palate is not rare, and is associated with general thickening of the mucous membrane. 8. Finally, the postnasal space may be obstructed by webs and neoplasms which can not be described in this communication. These here enumerated include the commonest only of these morbid conditions that simulate or are responsible for the existence and persistence of "adenoid" symptoms.

On the Removal of Tonsils in Adults. H. Lambert Lack.—The removal of tonsils in adults is not such a simple matter as it is in children: 1, on account of the danger of hemorrhage, which is much more common in patients over 15 years of age; and 2, the effect it may have upon the voice. The methods of removal are noticed by Lack, who remarks first on the electric cautery, which is suitable for much enlarged tonsils where removal is not necessitated by recurring tonsillitis and complete removal is undesirable. Tonsillotomy should never be performed in adults with very large tonsils, but in some cases where repeated attacks of tonsillitis occur and the tonsils are too small to be snared, they may be cut away to some extent. Removal with the cautery snare leaves a large charred wound in the throat with increased danger of infection, and is not favorably mentioned. The cold-wire snare is the only method applicable to cases of much enlarged tonsils and seems to have more advantages here than any other method. Enucleation by incision through the mucous membrane between the anterior pillar of the fauces and the anterior border of the tonsils, shelling out the tonsils, is not difficult to perform if care is taken to keep outside the tonsil capsule. General anesthesia, however, is advisable. There is little risk of hemorrhage; the tonsil is completely removed and in some cases of flat tonsil there is no other applicable method. Each case, however, must be judged by itself; there should be no routine method for all.

The Lancet, September 28.

The Diagnosis of Cancer of the Stomach. John C. Hemmeter.—The early diagnosis of cancer of the stomach is rare in the literature; the patients do not usually present themselves in time and decline to be submitted to methods most promising for early diagnosis. Hemmeter says: "The most important information from all the physical signs and symptoms and from the chemical and microscopic investigations may be arranged in the order of their diagnostic value as follows, but I do not desire to be dogmatic in this statement: 1. Chronic gastritis or nervous dyspepsia with progressive aggravation in spite of four weeks' proper treatment. 2. Progressive weakening of the peristaltic power. This can only be confused with the benign stenosis of the pylorus, but in the latter case—the benign stenosis—there is, as a rule, a normal or an excessive amount of hydrochloric acid. In malignant stenosis there is absence of hydrochloric acid and formation of lactic acid. The diagnosis between benign and malignant stenosis may be difficult at the beginning of the clinical observation of any case, but after two to four weeks of observation it should present no difficulties. 3. Progressive diminution in the amount of free hydrochloric acid with steady loss of peristaltic power. 4. The presence of large numbers of atypical and asymmetrical mitoses after gastric curettage, together with characteristic histologic changes in the glands previously described—especially in cases of motor insufficiency. With such clinical indications exploratory laparotomy should be undertaken, and where this step proved the diagnosis to be wrong, in my experience, it was discovered that conditions were present which necessitated operative interference anyway, such as, for instance, motor insufficiency from cicatrices, indurated ulcers, or adhesions. In this schema the diagnostic value of the Oppler-Boas bacilli, tumor, and lactic acid are not referred to because they are late signs. I do not wish to be understood to say, however, that a surgical operation should not be undertaken when these late signs are present. Many times even the presence of a tumor is not a contra-indication to an operation, because a malignant tumor in the stomach may be present, as I have noted on three occasions, and no signs of metastases of infection of the lymph glands were discoverable by a careful search at the necropsy." The diagnosis of carcinoma of the stomach is still in its rudimentary stage. The further development of the subject, the author thinks, does not depend so much upon the bacteriologic investigation as upon the pathologic and physiologic chemistry of the cell.

Syphilitic Affections of the Stomach. W. Soltau Fenwick.—It is thought that while the mouth and rectum commonly suffer from syphilitic lesions the stomach escapes, notwithstanding the evidence to the contrary. Syphilis may affect the stomach in three ways: 1. By the formation of gummata; 2, by producing endoarteritis; 3, by exciting chronic inflammation of the mucosa. Gummata of any size are rarely found. The tumor, which is often multiple, is usually in the submucous tissue of the pyloric region near the lesser curvature. It increases in size and its substance undergoes softening, which usually becomes destroyed and an ulcer is produced which has certain features distinguishing it from the simple variety. It is often irregular, scalloped or triangular. Its edges are thickened and undermined, while its wall and base are shaggy, cheesy, hemorrhagic or covered with firmly-adherent yellow slough. It is usually surrounded by an area of some degree of chronic inflammation and syphilitic manifestations occur in other portions of the abdominal viscera; perforation of the stomach has not been observed in these cases. Obliterative endarteritis affecting the gastric vessels must not be regarded as necessarily an indication of syphilis as it may be observed with chronic simple ulcer and other conditions. The syphilitic variety is rarely a primary complaint, and as far as Fenwick has observed is always associated with gummata in the liver, spleen, pancreas and elsewhere. It chiefly affects the smaller branches of the pyloric vessels and causes inflammatory thickening of the mucous membrane, interstitial hemorrhages and ulcerations. It may produce symptoms of chronic ulceration of the stomach or of dyspepsia followed by hematemesis. Chronic gastritis may be the direct or indirect result of syphilis. The latter is most common, and is due either to embarrassment of the gastric circulation from disease of the liver or spleen or to lardaceous degeneration of the vessels of the stomach, to secondary disease of the kidneys or to the specific cachexia. It does not differ histologically from the usual forms, and like them, usually subsides when the exciting cause has been removed. We should not fall into the mistake of many that every gastric ulcer occurring in syphilitics is due to syphilis. About 5 per cent. of all the population suffer from gastric ulcer from other causes and gastric irritation in a syphilitic subject may possibly be due to injudicious medication. Chronic syphilitic ulcer of the stomach is most common in men between 25 and 40, and in cases where secondary symptoms have been slight or rapidly removed by treatment. Pain is invariably present and nocturnal pain has been considered especially characteristic; this is also true of attacks of emesis during the night, though they may occur with simple ulceration. Anemia is invariably present, and the peculiar sallow complexion of many of the patients is suggestive of specific cachexia. As a rule the complaint fails to respond to ordinary means and may show a tendency to relapse even with anti-syphilitic remedies. Gastritis occurs both in hereditary and acquired syphilis, and is chiefly characterized by its chronicity and intractibility to ordinary treatment. The loss of flesh, anemia and debility are out of all proportion to local symptoms. The mild forms of gastritis occurring in adult life are practically undistinguishable from the alcoholic varieties, but in severe cases the anemia, debility,

etc., are suggestive of malignant growths. He has seen a number of cases where cancer has been diagnosed that were relieved by specific treatment, which is a great point of distinction in these cases. The subjects of gastric cancer are very intolerant of mercury and the iodids, which is the reverse with the syphilitic form. The gastric crises of locomotor ataxia occur at irregular intervals and are seldom excited by the ingestion of food. A few days' trial of iodid of potassium will usually clear up any doubt. Rest, of course, and other methods given for ordinary gastric disorders are advisable, but mercury should always be combined with the iodids as the latter are less effective without it. The patient should be warned as to the dangers of a relapse.

Bulletin Medical (Paris), August 17.

Medical Injections of Quinin into the Cerebrospinal Fluid. Jaboulay.—The subarachnoid injection of cocain produces extensive but transient analgesia; when quinin is thus injected, the analgesia is less in extent, but it lasts for two weeks. Jaboulay has found the latter an effective measure for the relief and possibly cure of painful, purulent cystitis; cancers of the rectum; sciatica, arthralgia of the pelvis and hip; neuritis of the leg; pelvic neuralgia; incontinence of urine, and inveterate onanism. He uses the quinin in a concentrated solution, .5 cg. to the cubic centimeter. He has found 5 cg., or even 2.5 cg. sufficient for the curative effect, while this amount is not large enough to cause neuritis or destructive lesions of the cauda equina. He makes the injection in the lumbar subarachnoid space. The analgesia induced includes the genital organs, bladder and rectum. It is accompanied by paresis of the corresponding muscles. With a larger dose it is possible to induce anesthesia of the foot and lower portion of the leg, suggesting that this measure may prove useful in the treatment of Little's disease. He points out that the varying results obtained by various surgeons in spinal cocainization is largely due to the temperature of the solution of cocain. When it is heated to 99.5 F. its diffusion is more rapid. If not warmed, it stays at the bottom of the subarachnoid cavity, and it loses .005 of its density when heated to 104 F. Both cocain and quinin should be used only for medical and not for surgical purposes, as surgical anesthesia can be obtained by simpler measures.

September 4.

Aid to Prognosis of Diphtheria. Rabot.—The subcutaneous injection of saline solution in a child with diphtheria may throw light on the prognosis. If the child voids more urine after it, without vomiting or diarrhea, the diphtheria will run a mild course, no matter how stormy the onset. But if the amount of urine is not increased, and the little patient vomits or has diarrhea, the prognosis is grave, even in apparently benign cases. The latter phenomena indicate that the toxins have affected the heart fibers, and the organ is thus unable to respond to the action of the saline solution.

Presse Medicale (Paris), September 21.

Some Experimental Experiences with Phototherapy. R. Romme.—Borissoff reports tests with dogs and rabbits which showed that the growth and development was retarded in young animals kept in dark rooms. Even when the largest and strongest animals were transferred to the dark rooms, by the end of the second week their growth was less in proportion than that of the control animals in ordinary light rooms. He compares the stimulus exerted by the light to that of exercise on a muscle. Drigalski found that the electric rays, far from possessing any bactericidal power, predisposed the animal organism to infection, and enhanced its gravity. This fact can not be due to the heat alone, as other animals kept at the same temperature, but not exposed to the electric light, proved much more resistant in all the tests. Strebel has found electric light baths applied as a therapeutic measure, effectual in curing soft chancres, leg ulcers, acne, and, in general, all ulcerating cutaneous lesions; he eliminates the heat rays by passing the light through a vessel containing copper sulphate solution. In rheumatic affections the results were inferior to those obtained by hot air, but the treatment proved more efficacious in arteriosclerosis, in fatty degeneration of the heart, in a few cases of bronchial catarrh, and occasionally in neuralgia. The effect was negative in nephritis.

Curable Gangrene of the Lids. H. Roger.—A robust man with no pathologic antecedents, was suddenly affected with spontaneous gangrene of the lids of one eye. It commenced with a simple patch of inflammatory edema, followed by fever for four days, the entire process developing to complete restitution in twenty-one days. The eye was not involved. Only one similar case could be found in the literature. A large aërobic micrococcus was cultivated from the serum, pathogenic for rabbits and guinea-pigs, but harmless for rats. The micrococci discovered in the lesions of gangrenous mammitis are also aërobic.

Treatment of "Thin Diabetes." P. Maucquaire.—Lancereaux applies the term "diabète maigre" to the glycosuria connected with an affection of the pancreas, in opposition to the "fat diabetes" of arthritic and gouty subjects. The pancreatic juice may be produced in excess in this variety of diabetes, or it may be deficient. Several comparative tests on rabbits are described, which suggest that the sugar produced in the organism by the transformation of starchy food, and the sugar generated in the tissues by autodigestion, pass into the liver. Here, in normal conditions, they are transformed into glycogen and deposited. The liver ferment, whose formation is dependent on the pancreatic zymases and the pancreatic juice itself, dissolves this stored glycogen as needed, and the sugar is transformed in the circulation into water and carbon dioxid. Absence of the pancreatic juice in an affection of the pancreas, entails the absence of the liver ferment. The glycogen in the liver is not dissolved, and the sugar which constantly arrives from the food or autodigestion, finding no room in the liver, continues to circulate in the blood until the kidneys separate it and eliminate it in the urine. The practical conclusions from this hypothesis are that the physician should not hesitate to administer pancreatin in cases of "thin diabetes" in a dosage as high as three to eight grams a day, if necessary.

Painless Application of Sublimate to Mucous Membranes. De Pierris.—The smarting produced by the application of water to the nasal mucous membrane is due to the lack of isotonicity between the molecular concentration of the blood and of the fluid employed. The smarting can be prevented by adding about 9 per cent. of salt, which renders the fluid isotonic with the blood. When this is done, sublimate can also be added, 1 to 10,000, or even 1 to 4000. It does not induce the slightest pain in this isotonic combination with saline solution, but otherwise it does.

Revue de Medecine (Paris), September.

Cerebellar Hereditary Ataxy. A. Thoma.—The Haud family, of Paris, is distinguished by the fact that five members of the family in two generations have presented the same curious ataxy with other cerebellar symptoms. The various cases were carefully studied. The autopsy findings in the case of Amelia, who succumbed last, at the age of 47, show the same anatomic foundation as all the others—a lesion in the cerebellum or cerebellar tracts. The cerebrospinal axis was exceptionally small in every case, but the lesion itself differed in nature and exact site in each. The cerebellum was small, but the spinal cord was still smaller in proportion. Actual degeneration was noted only at a few points, especially and invariably in the cerebellar tracts. Aside from this Haud family, Sanger Brown's is the only other instance known of family hereditary ataxy, and in his case the lesion extended through the cerebellar system in the cord while the involvement of the cerebellum itself was doubtful.

Two Cases of Sciatic Neuritis Caused by Mercurial Injections. Dopter.—After the unfortunate experience indicated in the title, Dopter made a study of the danger zone for these injections. He has established that the course of the sciatic nerve follows a line starting two fingers' breadth outside of the postero-superior iliac spine and terminating in the median axis of the posterior surface of the thigh. The danger zone extends 3 cm. each side of this line, from the sacro-sciatic foramen, where the nerve emerges, to the center of the dividing line of the buttocks below.

Revue Mensuelle des Mal. des Enfants (Paris), September.

Cocain Cause of Idiocy in Offspring. A. B. Marfan.—A healthy couple had two healthy children, when the father became addicted to the use of cocain. For years he was in the habit of taking as much as three grams a day, exclusively by the nose. Two children have since been born, both typical specimens of microcephalous idiocy.

Revue de Therapeutique (Paris), August 15 and September 1.

Influence of Certain Foods on the Gastric Juice. Potapow-Pracaitis.—In Schiff's experiments on dogs, he found that a marked peptogenic power was possessed by dextrin, bouillon, raw meat, bread, cheese, peptones, gelatin and black coffee. Pawlow found that Liebig's extract, bouillon, water, milk, gelatin and raw meat possess the property of increasing the secretion of gastric juice. In the research described in the present article, it was established that the results obtained by Schiff and Pawlow supplement and confirm each other. Certain substances, such as bouillon and raw meat, are both peptogenic and gastric juice-producing, or succagogue. The influence on the secretion of gastric juice is completely abolished when the substances are administered by the rectum, showing that the direct intervention of the nervous system is required for this sympathetic reflex secretion. On the other hand, the peptogenic effect is fully as marked when the substance is absorbed by the rectum as when absorbed by the stomach. The peptogenic effect is, therefore, transmitted by the intermediation of the blood.

Semaine Medicale (Paris), September 18.

Nodular Tuberculosis of the Prepuce. J. Sabrazés.—A lump the size and shape of an olive developed in the under surface of the prepuce, about 1.5 cm. above its free edge, in a man of 26. It simulated a sebaceous cyst, but it appeared about a year after the patient had noted dull pains in the renal and hypogastric regions and displayed other symptoms of slowly developing tuberculous lesions of the urogenital organs. Koch's bacillus was discovered in the urine, and also in the caseous masses which formed a large portion of the tumor. It was readily excised, and the patient was thus relieved of his most troublesome symptoms, and was able to resume his occupation.

Treatment of Malaria with Iodin. Regnault.—During an attack of malaria assuming the gastro-bilious form and rebellious to quinin, Regnault took a teaspoonful of a mixture of tincture of iodin and potassium iodid, 4 gm. of each, in 100 gm. of water. This was equivalent to 2 cg. of pure iodin, and he found that the chill was arrested in fifteen minutes and the skin resumed its functions. He has administered it to numbers of patients since, and always with the same result, the prompt subsidence of the attack. A second dose is rarely necessary. Quinin has to be taken before the attack; if it fails to prevent it, the iodin treatment is indicated during or, better still, at the commencement of the attack. On account of the incompatibility of iodin and quinin, the two should not be taken together.

Berliner Klin. Wochenschrift, September 2.

Relations Between Human and Bovine Tuberculosis. P. Baumgarten.—Twenty years ago Rokitansky conceived the idea that it might be possible to arrest or even to cure malignant tumors by the antagonistic action of the tubercle bacillus which was an article of belief at that day. He consequently considered himself justified in taking advantage of this possibility in the treatment of otherwise hopelessly doomed patients with inoperable carcinoma or sarcoma. As the tubercle bacilli of human and of bovine tuberculosis were considered identical, the latter were used for the purpose, and more than half a dozen patients were thus inoculated with considerable amounts of bacilli taken from cattle, and which had proved their extreme virulence in tests on rabbits. Most of the patients survived from several months to over a year, but, after the healing of the pustule induced by the injections, none of them exhibited any signs of tuberculosis, and neither macroscopic nor microscopic tuberculous lesions were discovered at any autopsy, although Baumgarten was himself prosector at the time and all passed through his hands. The inoculations had no noticeable effect on the patients, and the attempted treatment was abandoned. In 1893 one of Baumgarten's pupils inoculated two calves with tubercle bacilli, one in the eye with bacilli from the ox, and the other in the eye and flank with bacilli from tuberculous patients. One calf died in six weeks with all the symptoms and anatomic lesions of diffuse miliary tuberculosis, such as is seen in man. The second calf, inoculated with human tuberculosis, remained healthy, and, when killed several months later, no traces of either human or bovine tuberculosis could be discovered. The control rabbit died of generalized tubercular lesions in about five months. Baumgarten adds that he has not been able to find in the literature a single authentic instance of the transmission of human tuberculosis to cattle. He agrees with Koch that practically there is very little danger to man from bovine tuberculosis, but he is convinced of the identity of the bacilli and that external circumstances are responsible for their differences. The classic picture of human miliary tuberculosis was induced in the calf mentioned, and Tangl and Troje have also demonstrated that certain external factors, such as the fumes of iodoform, may modify the pathogenic properties of human tubercle bacilli to such an extent that they induce the bovine form of tuberculosis when inoculated into animals. The histologic identity of both forms is confirmed by the fact that the caseous process so characteristic of human tuberculosis, occurs likewise in the bovine tubercles, only it is frequently disguised by the rapidly succeeding calcification of the caseous masses. This has nothing to do with the essential disease process, and is often observed in the caseous masses in man. The extent of the calcification in animals is probably due to their larger proportion of calcium salts. The variability in the pathogenic properties of bacteria is a familiar fact. It is more than probable that the bacilli have adapted themselves to their habitat in the course of time, and lost their pathogenic properties for others. But until this is definitely established he observes that there should be no relaxation in the prophylactic measures employed, as further research may lead to opposite conclusions.

Treatment After Operation of Diffuse Purulent Peritonitis. T. Gluck.—The principles on which Gluck bases his after-treatment are exemplified in the smooth and rapid recovery of a man who had been gored by an ox. When he recovered consciousness he found his intestines lying between his knees, covered with blood, ditch water, fecal matters, dirt and sawdust, and exposed to the glare of the direct sunlight for hours. Gluck believes that warmth, moisture and the action of light, favor the healing of peritonitis or any intestinal lesion after an operation. After much experimental research on animals, applying the results to man, he constructed an apparatus in which the intestines are eventrated and received in a warm, moist, glass case, which allows the action of electric light and frequent irrigation. Cardiac insufficiency or paralysis frequently follows the reposition of the intestines after a laparotomy; this danger is entirely obviated, as the intestines are not replaced until all danger of shock is past. He mentions Fenton B. Turck's views with especial approval. After the operation the patient is placed on a water mattress on a frame, to which the box for the intestines is fastened. The whole is then placed in an empty bathtub, and Schäfer's warm water regulator is attached. Gluck has thus treated cases of gangrenous hernia, volvulus after perforation of the appendix, and peritoneal tuberculosis, besides the ordinary diffuse purulent peritonitis. His results have been so favorable that he considers this method as a brilliant progress in surgery, although he claims no priority for it, as it is merely the legitimate outcome of the general trend of abdominal surgery, and as the technique is still far from perfect. In certain uncomplicated cases of diffuse peritonitis, a small laparotomy with lavage of the peritoneum may be sufficient, using a 3 per cent. solution of salt and boric acid or of 1 per cent. salicylic acid, and glass drainage or tamponing. The continuous bath is liable to infect the wound. The abdominal wound should not be sutured at all, but should be left wide open. By this

means the peritoneum can be thoroughly cleansed and the organism relieved of the task of resorbing, eliminating and overcoming the infection. *Restitutio ad integrum* becomes possible, especially in case of tuberculous processes. Gluck uses the apparatus alone or in combination with a loose tampon over which is drawn a gauze bag. When the strings of the bag are drawn up like those of a tobacco pouch, the enclosed intestines are protected. Another method is to pass long silk threads through the fascia and muscles of the wound and tie them, after loosely piling up a mound of gauze in the wound, over which the threads are tied. The box for the intestines might be modified so as to be used even during the operation.

Balancing Extension. F. Cramer.—The foot of the patient is attached to a weight suspended from a pulley at the head of the bed. The rope passes over the pulley on a frame above; under a pulley fastened to his ankle; over a second pulley above, and finally under a second pulley on the tip of the foot; it then fastens to a hook in the frame above close to the foot of the bed. The rope above the patient's leg thus outlines a W. Another weight is suspended from a pulley at the foot of the bed, not far above the plane on which he lies, and this rope is attached to his heel. The limb is thus in continual extension, but at the same time considerable movement is possible.

Centralblatt f. Innere Medizin (Leipsic), August 24.

Leucocytosis in an Outbreak of Sweat. W. Hames.—The leucocytes increased by 3000 and 5000, and in some cases to double the previous amount in all the children examined, except those in cachexia, fifteen minutes after either natural or induced sweating. Half an hour after the children were wiped, dressed and transferred to a freshly made bed, the leucocytes had returned to the normal number. About twenty-nine children were tested and the results confirm the function of positive chemotaxis exerted by the hydrotics, and antipyretics in febrile conditions, as well as by the spontaneous or induced sweats in both health and disease.

September 7.

Gymnastics on the Sickbed. H. Zeehuisen.—During convalescence from infectious disease, and in conditions requiring rest in bed, great benefit may be derived from systematic gymnastics under the physician's instructions. Convalescence is shortened, and recovery is more complete than without these gymnastics. As a typical example is described the case of an elderly woman, with fatty degeneration, arrythmia and edema of the legs. Medical treatment and rest had not alleviated any of the symptoms. Zeehuisen instituted a series of gymnastic movements as she lay in bed; each were performed but once, and with first one leg and then the other, three for the thigh and one for the knee. At first the movements were passive, then active and then against slight resistance, always in the morning. After two weeks each movement was repeated twice. The success of these measures in the course of two months was remarkable. Pulse, respiration and skin were normal; after a course of treatment at Bad Nauheim the patient has been completely cured for years and to date. These bed exercises are especially beneficial for bedridden obese patients, in certain gynecologic affections, in gout and particularly in traumatic neuroses.

Dermatologische Centralblatt (Berlin), September.

The Bottini Operation for Hypertrophied Prostate. C. Stern.—With chronic, complete retention and a hard prostate, the Bottini operation with Freudenberg's modification of Bottini's original galvanocautery, is a more effective procedure than any other known to date. All it claims to accomplish is to make an opening in the dam which is holding back the urine. It is safer than continual catheterization in the hands of the ordinary patient, but as in the case of a colleague who catheterized himself with ease and absolute asepsis, circumstances may render it superfluous. It should be reserved for cases which are persistently rebellious to ordinary measures.

Deutsche Med. Wochenschrift (Leipsic), September 26.

Treatment of Dysentery with Calomel. A. Plehn.—The method of treating dysentery by small doses of calomel, inaugurated by Plehn, has abundantly proved its efficacy in his experience during the last three years at Cameroon, and also in South America, where it has been introduced. He orders first two tablespoonfuls of castor oil, which clears up the diagnosis and cleanses the intestines. The next morning he gives a tablet of 3 cg. of calomel every hour for twelve hours, continuing this treatment the next and the following day, suspending it at night. After each tablet the patient must rinse his mouth thoroughly with a solution of tincture of krameria or of salicylic acid. After three days of the calomel he substitutes a tablet of .5 gm. of bismuth every hour for twelve hours, continues this for three days and then reduces the amount to 6 gm. a day, until all pathologic symptoms have vanished, when he continues with 3 gm. a day for a time longer. A number of cases are described in detail showing the efficacy of this method of treatment. The calomel probably acts as a disinfectant. The germs causing the dysentery develop throughout the large intestine, but it is the products of their metabolism which cause the pain, the increased secretion, the disturbance in the intestinal resorption and the intense irritation of the intestinal walls. Under the action of these chemical toxins the mucous lining is destroyed, ulcerative processes develop and secondary infection is liable to occur, frequently due to the amoebæ. Calomel given continuously as described, kills the germs and the production of their toxins is arrested. The acute irritation of the intact mucous membrane rapidly subsides. If the ulcerations are already in progress, they may require some time to heal, but healing is promoted by a strictly fluid diet and the bismuth. Certain liver affections subsequent to slight intestinal infections, may likewise be due to the toxins secreted, as they rapidly recover under this calomel treatment of the primary intestinal infection. He is inclined to believe that the same treatment might prove effective in early cases of typhoid fever and in cholera, but he has had no opportunity to test it in these diseases. He recommends others to try six or eight doses of calomel every two hours in mild cases of dysentery.

A Case of Tuberculosis of the Knee Benefited by Koch's New Tuberculin. Brunzlow.—The patient was a lad of 14, who had suffered from a tubercular affection of the knee since 1897. After surgical treatment of the joint, the conditions became aggravated, and the general condition grew rapidly worse. He was then treated with tuberculin (T. R.), commencing with 1/1000 mg., and the beneficial effect was rapidly apparent, as the lad gained four and one-half pounds in the first week. He was treated with four separate courses of tuberculin, in two years, gradually increasing the dose from .0005 mg. to 2 mg. each time, carefully avoiding reaction and waiting until every trace of induced elevation of temperature had vanished before injecting the tuberculin again. The benefit was apparent in the rapid increase in weight and the disappearance of all local symptoms. At present, the joint is normally movable and free from pain, but the muscles are a little weaker than in the other knee, and a faint grating sound can be heard on movement. There is still a slight reaction to a test-injection of old tuberculin, and consequently the case is not a cure. However, the results show such improvement in every respect, with constant gain in weight, that they should encourage others to try tuberculin as a therapeutic measure in rebellious cases of surgical tuberculosis.

Treatment of Exudates. E. Homberger.—The fluids of the body always seek to maintain an osmotic balance. If we assume that the blood and an exudate or transudate have the same osmotic tension, dilution of the blood will be followed by the passage of the excess of water into the exudate, reducing the osmotic tension of the latter, while the concentration of the blood increases in proportion. As the blood becomes more concentrated, the exudate is reabsorbed under the action of the same laws of osmosis. Homberger states that by utilizing these principles we have an effective means at our disposal of promoting reabsorption of exudates and transudates. The blood can be diluted by the administration of water. It is absorbed more readily if taken in small amounts in an empty

stomach, and most rapidly of all, when the water is slightly acid and weak in salts. Nature demands water in infectious fevers and lemonade not only relieves the thirst, but has a directly curative influence on the disease by promoting osmosis. The benefit of saline infusion is directly due to the water. In diabetes, the sugar in the blood causes absorption of water from the tissues, in Nature's attempt to restore the balance of osmotic pressure. The overfilled vascular system empties the excess of water into the kidneys, while Nature calls for more water to supply the demand, thus explaining the polyuria and thirst in diabetes. Homberger concludes by stating his belief that in therapeutics the internal use of water is as important as its external use, and that it can be harmful only in exceptional cases. Simmonds announced last year that in none of the autopsies which he has conducted was he able to detect any indications that the infusion of saline solution had been responsible for dilatation of the right ventricle. The great objection, that a weak heart is not able to stand it, is thus shown to be unfounded.

Lamp for Photography on a New Principle. Sophus Bang.—All the lamps hitherto used for phototherapy were originally constructed for optical purposes. None of them aimed to produce a cold light, rich in ultra-violet rays. Bang announces that he has devised a lamp in which the materials were selected for their properties in the spectrum. He finds iron most suitable for the electrodes, instead of carbon tips, and keeps it cool by a circulation of water inside. The iron tips do not generate rays, and the light is actually an arc light, as the rays are generated in the space between the tips. Its bactericidal power is sixty times greater than that of the ordinary arc light. Its effect on the skin is likewise much more intense. Five minutes' exposure at a distance of one yard will induce a severe erythema of several days' duration. For local treatment, he has designed a small lamp, which, with the compressor, is not much larger than an ordinary tablespoon. The whole is placed directly on the skin, as there is so little heat that a distance of 1 to 1.5 cm. is ample. With 5 amperes and 40 volts, it is possible to obtain in five minutes as strong a reaction over 10 sq. c., as has hitherto been obtained with an apparatus of 60 amperes and 50 volts in one and one-quarter hours. As the light is so powerful, neither concentration nor automatic regulation is required, and it can thus be very cheaply constructed.

Three Cases of Pure Hereditary Ataxia. E. Weber.—A family is described in which three children present the typical clinical picture of Friedreich's disease. The parents are healthy and well-to-do, and have two other healthy children. The affection commenced about the sixth year in each, and can be observed in the three patients in the incipient, established and advanced stages. The youngest is 7, and the oldest 18 and bedridden. The ataxia in his case is more pronounced than Weber has ever witnessed in any tabetic subject.

Value of Colchicin in Gout. K. Kuester.—Since restricting himself to a more vegetable diet and avoiding meat, Kuester has found that he suffers less with gout, to which he is naturally and hereditarily predisposed. An occasional attack still occurs, and he finds relief in colchicin alone. He takes it in pills, .5 cg. colchicin to 1.5 gm. each of licorice extract and powder, to make 20 pills. Two of these will frequently abort a mild attack, and four pills in the course of two days reduce the symptoms very materially and shorten the course of the attack. Thus, after reclining for one day, he is soon able to attend to his practice, and is agile again in eight to ten days, with all the gouty deposits absorbed. Without the colchicin, he has to recline for two weeks and is stiff and aching for three weeks longer. His personal experience has been confirmed by that of gouty patients for whom he has prescribed the colchicin.

Treatment of Meniere's Symptom-Complex. G. Heermann.—Certain symptoms in this affection can be traced to the ears, others to the nerves, and others to a general cause. In order to differentiate and apply appropriate treatment, Heermann has been appealing to his colleagues to report their experiences. He sends a blank circular on demand and gratefully receives all communications addressed to him at Kiel. During the acute attacks he states that a position in which the vertigo is attenuated can almost always be found, but the patient is unable to find it for himself. He must be made to recline, with the upper part of the body slightly raised and the head turned toward the sound side. Both the nausea and the vertigo become much attenuated when the correct position is found. The bromids are the only internal remedies of any value. In case of syphilitic antecedents specific treatment is indicated. If there is a history of a preceding chronic, suppurating otitis media, the semi-circular canal must be opened up, and a cholesteatoma is sometimes found. The Ménière symptoms may appear during the course of a dry catarrh of the middle ear. Besides the usual treatment of this condition, Heermann advocates pilocarpin. He commences with one-tenth of a Pravaz syringeful of a 2 per cent. solution, increasing by one-tenth daily until copious sweating is induced; usually less than seven-tenths are required. The patient must stay in bed while sweating. The pilocarpin banishes the vertigo, and frequently improves the hearing, but is contraindicated in case of elderly or corpulent persons. In apoplectiform deafness it has worked wonders in his experience. He also found thyroid treatment beneficial in two cases with goiter. The patient may have forgotten his old ear affection when the Ménière symptoms appear. The vertigo in such a case is liable to be attributed to the stomach. There is frequently pronounced stagnation in the vascular system and constipation. Appropriate local treatment and out-of-door exercise may improve the hearing with the general health, and the vertigo vanishes. He describes several instructive examples. One patient, for instance, with bilateral chronic catarrh of the middle ear, exhibited the Ménière symptoms and deafness during and after a pregnancy. Treatment of the ear and twenty-one injections of pilocarpin, with exercise, resulted in the cure of all the symptoms including the deafness. They all returned during another pregnancy, but yielded as before. When the Ménière symptoms develop on a neuropathic basis, operation on the ear is liable to be distinctly injurious. It is in these cases that quinin, electricity and similar measures score their triumphs. Quinin should be completely avoided by the aurist, as well as the salicylates, as they expose the functions of a diseased ear to the most serious dangers.

To Test the Permeability of the Nose. F. Bruck.—The Journal described Glatzel's mirror, in the issue for September 28, p. 874. Bruck points out that it tests the permeability of the nose during expiration only, while it affords no information in regard to inspiration. The latter may be hindered by a floating polyp, sucking in of the nostrils or other impediment affecting inspiration alone.

Therapeutische Monatshefte (Berlin), August.

Treatment of Scrofulosis and Tuberculosis by Inunctions of Cod-Liver Oil. B. Rohden.—For five years Rohden has been using a mixture of 50 per cent. deodorized cod-liver oil, balsam of Peru, and oil of cinnamon, lemon and thyme, combined with lanolin, glycerin and an alkali, to rub into the skin of scrofulous and tuberculous children. He reports extremely satisfactory results from this inunction with "dermosapol," as he calls the mixture. It is a stable, aromatic preparation, of which every particle is absorbed. It is rubbed into the chest and back in the morning, and into the abdomen, buttocks and limbs at night. About 100 gm. are required for ten or twelve days. The cells and tissues are influenced by the cod-liver oil and the lymph becomes saturated with the ethereal oils and the balsam. Tuberculosis on a scrofulous basis is exceptionally benefited by this treatment, especially glandular and joint affections and lupous lesions.

Artificial Respiration in Treatment of Bronchitis. Heermann.—An apparently moribund, six-months' infant in progressing bronchitis was saved by artificial respiration, including Schultze's swinging and pressure on the false ribs, maintained for two hours. Since then Heermann has ordered artifical respiration in every severe case of bronchitis in a child. The nurse or the parents are instructed to apply slight pressure with one hand on the false ribs during expiration,

changing the hand frequently. Expectoration is promoted, respiration deepened, the rapid breathing becomes slower and the pulse stronger. The expulsion of accumulated secretions is promoted by this measure, and the threatening paralysis of the muscles of respiration averted. The procedure is repeated several times a day for half an hour at a time.

Suturing the Tissues Without Foreign Material. F. SCHULTZE.—The conditions of success with the method of suturing which Schultze has been using with great satisfaction for two years, are complete hemostasis, and normal elasticity of the skin. The lips of the wound are coaptated and a row of Roser's torsion forceps is applied .5 to 1 cm. apart to hold the lips together. Cotton-collodion dressings are then applied in the interspaces. As soon as the collodion is dry, the forceps are removed, and a protecting bandage applied over the whole.

September.

Dietetic Treatment of Pregnancy. PROCHOWNIK.—Delivery can be almost certainly much facilitated in women with a small conjugata vera, not less than 8 cm. in diameter, by restricting the fluids to 500 c.c. a day, with 130 to 160 albumin, 80 to 130 fats and 100 carbohydrates, the total averaging 1800 to 2000 calories. Prochownik has now a record of 17 personal cases, and 31 collected in the literature, with a total of 62 births, all the children being alive at the date of publication. The previous births had been extremely difficult and tedious, and many of the children had died. On the above diet for the last ten or twelve weeks all the deliveries were much easier. With a conjugata of less than 8 cm. artificial premature delivery is the only resource and the precautionary diet is unnecessary. In women with normal pelves, but debilitated from any cause, congenital chlorosis, hemorrhages, etc., he commences dieting treatment early in the pregnancy, with repose in bed or reclining out of doors, for several weeks, better away from the home environment. The patients are encouraged to take as much albumin, fats, cream and fluids as possible, with frictions, gentle massage and small amounts of iron. To develop the lacteal secretion in women whose mothers and grandmothers had been unable to nurse their children, he orders a diet rich in carbohydrates, with massage of breasts, and reports 7 cases in detail, showing benefit in 2. He also tabulates 5 cases of obesity in which he forbade soups, sweets, etc., and ordered exercise, massage of the entire body, except the stomach, and restricted the fluids to 500 or 600 c.c., with 120 to 130 gm. bread and other food to taste, but not in large amounts nor much at a time. He commences this dieting treatment of pregnant women with a tendency to obesity, as early as possible. He pleads for a more general study of this subject. The possibility of its efficacy is now demonstrated beyond question. It only remains to work out the details. He states that women in tropical climates, with their vegetable and fruit diet, usually bear children more easily than the women of the north, although the pelvis averages smaller in tropical races.

Wiener Med. Wochenschrift, August 31.

Serum Treatment of Erysipelas. V. JEZ.—The serum is derived from the same patient on whom it is used. It always induces a reaction, evidenced by a rise of temperature after one or two hours, and rapid improvement of all the symptoms. The number of leucocytes in the blood increases while the toxic substances are eliminated in the urine, as shown by its increased toxicity. No after-effects were noted in the ten cases in which Jez tried this serum treatment. If 5 to 10 gm. are not enough to induce the reaction, he increases the amount. The serum is taken from a blister artificially produced for the purpose.

Epilepsy Cured by an Intercurrent Disease. M. TURNOWSKY.—The three cases related all occurred under Turnowsky's personal observation, continued for many years. The first was a man of 38, who had from fifteen to twenty seizures on some days, the epilepsy dating from his seventeenth year, until 1887, when it was completely cured by an attack of croupous pneumonia. The second was a woman of 34, with five or six seizures during the month, between the age of 20 and 25. At this time she contracted pneumonia, and has had no seizure since. The third patient was a boy of 12, who used to have ten to fifteen seizures a day between the age of 2 and 6. At the latter age he contracted scarlet fever, and since then has been completely cured of his epilepsy. The cure in these cases has persisted respectively fourteen, ten and six years. He concludes with the suggestion that it would not be such a great risk to send an epileptic to a locality where pneumonia was endemic, or to expose an epileptic child to scarlet fever, as these cases, carefully observed, in addition to those on record in the literature, would fully establish the possibility of the disappearance of epilepsy after an intercurrent infectious disease.

Janus (Amsterdam), September.

Progress in the History of Medicine. H. F. A. PEYPERS.—"The universities in France and Germany are now discussing measures to give the history of medicine a larger place in the curriculum. In America many of the principal medical schools have a chair for the instruction of history of medicine. Dr. Sarah Hackett Stevenson, who is professor of obstetrics, ethics and the history of medicine at the Woman's Medical School, at Chicago, interests us particularly, as the combination of ethics with the history of medicine is such an excellent idea. This association is as rare in medical curricula up to the present time, as the presence of a woman in the faculty." Havana has a professor for the history of medicine and another for the history of pharmacy. From Australia comes an important work by Dr. W. J. Stewart McKay, entitled "History of Gynecology Among the Ancients." It seems remarkable to receive a serious work on the history of medicine from such a remote point as Sydney, so far from the universities and reference libraries of the old world.

Extragenital Endemics of Syphilis in Hungary. E. WEYNER.—Three of these endemics are on record; one was traced to a drinking cup used by the children of a school in which one of the teachers was syphilitic. In both the others, the infection occurred by arm to arm vaccination. In the latest endemic, 270 persons were infected by this means.

Gazzetta Degli Ospedali (Milan), September 22.

Koch's Views of Tuberculosis. E. MARAGLIANO.—The destructive action of the gastric juice and the auto-sterilization of the intestines recently promulgated by Kohlbruegge, explain the rarity of tuberculosis of the intestines from food infected by the tubercle bacillus, as well as from the bacilli in the sputa swallowed by tuberculous patients. This argument has therefore little value as cited by Koch to sustain his theory of the non-transmissibility of bovine tuberculosis to man. Maragliano has established that killed cultures of human tubercle bacilli cause intense toxic phenomena in cows and goats, showing that these animals are susceptible to the toxins of human tuberculosis, and, therefore, necessarily to its bacilli. Michelazzi has recently published the results of study of the prolonged use of sterilized milk from tuberculous cows. He demonstrates that the milk from a tuberculous animal, even if the teats are intact, and no bacilli pass into the milk, is yet extremely injurious, as the serum of the milk is toxic, even more toxic than that of the blood. The amount of toxin in the milk varies with the severity of the tuberculous process, but its toxic properties are unaltered, and are not affected by sterilizing the milk by heat. A chronic intoxication of the organism ingesting the milk is determined in time. His experiments at Pisa indicate that the profound marasmus accompanying tuberculosis in man and animals, is the result of the action of the toxins resulting from the presence of the tubercle bacilli, thus confirming Maragliano's assertions that tuberculosis is preeminently a toxicosis.

Serotherapy of Whooping Cough. T. SILVESTRI.—About 120 c.c. of blood were drawn from the arms of two children recovering from whooping cough. It was mixed with equal parts of saline solution and shaken up with 1 per cent. of chloroform and set aside to settle for twenty-four hours. It was then filtered and from 15 to 22 c.c. were injected into five other children with whooping cough. In two very severe cases the injection was repeated after five days. The effect of the serum treatment was evident at once. The general symptoms rapidly

vanished and the cough and broncho-pneumonic phenomena also subsided completely in from eight to eleven days.

Giornale Delle Accad. di Med. di Torino, July.

Severe Hemorrhage from the Ear. G. GRADENIGO.—Rohrer has recently related a case of severe hemorrhage from the ear, due to varices or bluish dilatations of the veins on both tympanic membranes. In Gradenigo's case the hemorrhage occurred during a paracentesis of the membrane on suspicion of acute otitis from the symptoms observed. There was no inflammation, but the incision opened an angiomatous tumor, with threatening arterial hemorrhage. The tumor was located just inside the membrane and may have been an aneurysmal dilatation of some abnormally diverging artery, but was more probably an angiomatous tumor with extensive dilatation of the vessels.

Hot Baths in Pneumonia. A. BORMANS.—When the fever goes above 39.5 C. (103 F.), Bormans places the patient in a bath tub of water at 40 C. (104 F.), first applying an ice-cap to his head and cooling the face with ice. As soon as the patient is immersed, water is added to raise the temperature of the bath to 44 C. (111 F.) and the temperature is maintained at this point for fifteen minutes, when the patient is returned to bed. The effect is extremely beneficial; the relief is almost immediate. The patient sweats profusely and his agitated delirium is quieted. In 12 cases thus treated, the crisis occurred on the fourth day in 3, the fifth day in 1, the sixth day in 4, the seventh day in 3, and the eighth day in 1. One patient died the eighth day with cerebrospinal meningitis. The afflux of blood to the periphery relieves the circulation in the lungs and the sweat eliminates a large proportion of the toxins. These hot baths are contra-indicated, of course, in case of heart disease or arteriosclerosis, but in all other conditions the benefit derived should cause them to be generally adopted. Bosc recommends hot baths in all the acute infectious diseases of children, but Giappone was the first to advocate baths of this temperature. Ortner reports excellent results from them in his "Manual of Therapeutics," published at Vienna last year. He orders them in bronchitis and pneumonia. The blood pressure usually drops slightly during the bath, but rises later, and surpasses what it was before the bath. The temperature may rise a fraction of a degree, and the pulse is slightly increased. In a few cases the blood pressure remained slightly below what it was before the baths, but the patient's euphoria and sweat were pronounced in every case.

New Patents.

Patents of Interest to Physicians, Issued September 17 and 24:

683,012. Optical instrument. Henry H. Hill, St. Louis, Mo.
682,936. Hernial truss. George V. House, Mount Vernon, N. Y.
682,854. Stopper for water-bags. Charles E. Longden, Hampden, Conn.
682,832. Speculum. J. Gordon McPherson, Toronto, Canada.
682,638. Eye-tester. Henry D. Reese, Abbeville, S. C.
682,650. Bed-pan. George Thornton, F. D. Freeborn and W. Hiller, Randolph, N. Y.
35,087. Design, suppository. Henry H. Foringer, Eria, Pa.
683,099. Syringe. Arthur E. Bonesteel, Central City, Colo.
683,380. Obstetrical appliance. Patrick F. Cassidy, Boston, Mass.
683,044. Bed-pan. Richard E. Holder, Columbus, Ind.
683,216. Therapeutic battery. Joseph A. Minturn, Indianapolis, Ind.
683,192. Apparatus for assisting the hearing. Alfred F. Watch, Philadelphia, Pa.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review as dictated by their merits, or in the interests of our readers.

DICTIONARY OF PHILOSOPHY AND PSYCHOLOGY, Including Many of the Principal Conceptions of Ethics, Logic, Anesthetics, Philosophy of Religion, Mental Pathology, Anthropology, Biology, Neurology, Physiology, Economics, Political and Social Philosophy, Philology, Physical Science, and Education, and Giving a Terminology in English, French, German and Italian. Written by Many Hands and Edited by James Mark Baldwin, Ph.D. (Princeton), Hon. D.Sc. (Oxon.), Hon. LL.D. (Glasgow), Stuart Professor in Princeton University. With the Co-operation and Assistance of an International Board of Consulting Editors. In Three Volumes, with Illustrations and Extensive Bibliographies. Vol. I. Cloth. Pp. 644. Price, $5.00. New York: The MacMillan Co. 1901.

THE AMERICAN ILLUSTRATED MEDICAL DICTIONARY. For Practitioners and Students. A Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry and Kindred Branches, Including Much Collateral Information of an Encyclopedic Character, Together with New and Elaborate Tables of Arteries, Muscles, Nerves, Veins, etc.; of Bacilli, Bacteria, Micrococci, Streptococci; Eponymic Tables, Diseases, Operations, Signs and Symptoms, Stains, Tests, Methods of Treatment, etc. By W. A. Newman Dorland, A.M., M.D., editor of the "American Pocket Medical Dictionary." Second Edition, Revised. Leather. Pp. 770. Price, $4.50 net. Philadelphia and London: W. B. Saunders & Co. 1901.

PROGRESSIVE MEDICINE. A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. Assisted by H. R. M. Landis, M.D., Assistant Physician to the Out-Patient Medical Department of the Jefferson Medical College Hospital. Volume III. September, 1901. Diseases of the Thorax and Its Viscera, Including the Heart, Lungs, and Blood Vessels—Dermatology and Syphilis—Diseases of the Nervous System—Obstetrics. Cloth. Pp. 428. Price, per annum, in four volumes, $10.00. Philadelphia and New York: Lea Brothers & Co. 1901.

AN INTERNATIONAL SYSTEM OF ELECTRO-THERAPEUTICS. For Students, General Practitioners, and Specialists. By Numerous Associated Authors. Edited by Horatio R. Bigelow, M.D., Permanent Member of the American Medical Association. Second Edition. Revised and brought up to date, with several New Departments, Embodying the Most Recent Developments of the Science. Edited by G. Betton Massey, M.D., Ex-President and Fellow of the American Electro-Therapeutic Association. Thoroughly Illustrated. Royal Octavo. Pp. x-1147. Price, $6.00. Philadelphia: F. A. Davis Company. 1901.

PATHOLOGICAL TECHNIQUE. A Practical Manual for Workers in Pathological Histology and Bacteriology, Including Directions for the Performance of Autopsies and for Clinical Diagnosis by Laboratory Methods. By Frank B. Mallory, A.M., M.D., Assistant Professor of Pathology, Harvard University Medical School; and James H. Wright, A.M., M.D., Instructor in Pathology, Harvard University Medical School. Second Edition, Revised and Enlarged. With 137 Illustrations. Cloth. Pp. 432. Price, $3.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

A TREATISE ON THE ACUTE, INFECTIOUS EXANTHEMATA. Including Variola, Rubeola, Scarlatina, Rubella, Varicella, and Vaccinia, with especial reference to Diagnosis and Treatment. By William Thomas Corlett, M.D., L.R.C.P. Lond. Professor of Dermatology and Syphilology in Western Reserve University. Illustrated by 12 Colored Plates, 28 Half-tone Plates from Life, and 2 Engravings. Pages viii-392. Sold only by Subscription. Price, Extra Cloth, $4.00 net, Delivered. Philadelphia: F. A. Davis Company. 1901.

MANUAL OF CHEMISTRY. A Guide to Lectures and Laboratory Work for Beginners in Chemistry. A Text-Book Specially Adapted for Students of Medicine, Pharmacy, and Dentistry. By W. Simon, Ph.D., M.D., Professor of Chemistry in the College of Physicians and Surgeons of Baltimore. Seventh Edition, Thoroughly Revised. With 66 Illustrations, 1 Colored Spectra Plate, and 8 Colored Plates, Representing 64 Chemical Reactions. Cloth. Pp. 613. Price, $3.00. Philadelphia and New York: Lea Brothers & Co. 1901.

NERVOUS AND MENTAL DISEASES. By Archibald Church, M.D., Professor of Nervous and Mental Diseases, and Head of Neurological Department, Northwestern University Medical School, and Frederick Peterson, M.D., Chief of Clinic, Department of Nervous and Mental Diseases, and Clinical Lecturer on Psychiatry, Columbia University. Third Edition, Revised and Enlarged. Cloth. Pp. 870. Price, $5.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

HUMAN PHYSIOLOGY. Prepared with Special Reference to Students of Medicine. By Joseph Howard Raymond, A.M., M.D., Professor of Physiology and Hygiene in the Long Island College Hospital, New York City. Second Edition, Entirely Rewritten and Greatly Enlarged. 443 Illustrations, 12 of them in Colors, and 4 Full-page Lithographic Plates. Cloth. Pp. 668. Price, $3.50 net. Philadelphia and London: W. B. Saunders & Co. 1901.

INTERNATIONAL DIRECTORY OF LARYNGOLOGISTS AND OTOLOGISTS. Containing Names and Addresses of Practitioners Engaged in the Study and Practice of Laryngology and Otology. Compiled by Richard Lake, F.R.C.S., Eng. Published under the Auspices of the Journal of Laryngology, Rhinology and Otology. Second Edition. Revised and Enlarged. Leather. Pp. 124. Price, $1.25. London: Rebman, Ltd. 1901.

ELECTRICITY IN MEDICINE AND SURGERY, Including the X-Ray. By William Harvey King, M.D., Editor of the Journal of Electrotherapeutics. In Two Parts. With a Section on Electro-physiology, by W. Y. Cowl, M.D., Berlin, Germany, and a Section on the Bottini Operation, by Albert Freudenberg, M.D., Berlin, Germany. Cloth. Pp. 296. Price, $3.50. New York: Boericke & Runyon Co. 1901.

DOSE-BOOK AND MANUAL OF PRESCRIPTION-WRITING: With a List of the Official Drugs and Preparations, and the More Important Newer Remedies. By E. Q. Thornton, M.D., Ph.G., Demonstrator of Therapeutics, Jefferson Medical College, Philadelphia. Second Edition, Revised and Enlarged. Leather. Pp. 362. Price, $2.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

TRANSACTIONS OF THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION. Complete account of Ninth Annual Meeting held at Washington, D. C., September 19, 20 and 21, 1899; also Tenth Annual Meeting held at New York City, September 25, 26, and 27, 1900. Illustrated. Pages xv-391. Price, Extra Cloth, $2.00 net, Delivered. Philadelphia: F. A. Davis Company. 1901.

A PRACTICAL TREATISE ON DISEASES OF THE SKIN. By John V. Shoemaker, M.D., LL.D., Professor of Skin and Venereal Diseases in the Medico-Chirurgical College and Hospital of Philadelphia.

Fourth Edition, Revised and Enlarged with Chromogravure Plates and Other Illustrations. Cloth. Pp. 892. Price, $5.00. New York: D. Appleton & Co. 1901.

A MANUAL OF THE PRACTICE OF MEDICINE. By George Roe Lockwood, M.D., Professor of Practice in Woman's Medical College of New York Infirmary. Second Edition, Revised and Enlarged. With 79 Illustrations and 20 Full-page Plates. Cloth. Pp. 847. Price, $4.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

A TEXT-BOOK OF OBSTETRICS. By Barton Cooke Hirst, M.D., Professor of Obstetrics in the University of Pennsylvania. Third Edition, Thoroughly Revised and Enlarged. With 704 Illustrations, many of them in Colors. Cloth. Pp. 873. Price, $5.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

A LABORATORY COURSE IN BACTERIOLOGY. For the Use of Medical, Agricultural, and Industrial Students. By Frederick P. Gorham, A.M., Professor of Biology, Brown University. With 97 Illustrations. 12mo. Volume. Cloth. Pp. 198. Price, $1.25 net. Philadelphia and London: W. B. Saunders & Co. 1901.

THE PRINCIPLES OF HYGIENE: A Practical Manual for Students, Physicians, and Health Officers. By D. H. Bergey, A.M., M.D., First Assistant, Laboratory of Hygiene, University of Pennsylvania. Illustrated. Cloth. Pp. 495. Price, $3.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

MODERN OBSTETRICS: GENERAL AND OPERATIVE. W. A. Newman Dorland, A.M., M.D., Assistant Demonstrator of Obstetrics, University of Pennsylvania. Second Edition, Rewritten and Enlarged. Cloth. Pp. 797. Price, $4.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

A TEXT-BOOK OF EMBRYOLOGY. By John C. Heisler, M.D., Professor of Anatomy in the Medico-Chirurgical College, Philadelphia. Second Edition, Thoroughly Revised. Illustrated. Cloth. Pp. 405. Price, $2.50. Philadelphia and London: W. B. Saunders & Co. 1901.

A TEXT-BOOK OF BACTERIOLOGY. By George M. Sternberg, M.D., LL.D., Surgeon-General, U. S. Army. Illustrated by Heliotype and Chromo-lithographic Plates and 200 Engravings. Second Edition, Revised. Cloth. Pp. 707. Price, $5.00. New York: Wm. Wood & Co. 1901.

A TEXT-BOOK OF DISEASES OF WOMEN. By Charles B. Penrose, M.D., Ph.D., formerly Professor of Gynecology in the University of Pennsylvania. Fourth Edition, Revised. Cloth. Pp. 539. Price, $3.75 net. Philadelphia and London: W. B. Saunders & Co. 1901. .

A MANUAL OF BACTERIOLOGY. By Herbert U. Williams, M.D., Professor of Pathology and Bacteriology in the Medical Department of the University of Buffalo. With 89 Illustrations. Cloth. Pp. 290. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co. 1901.

LIBERTINISM AND MARRIAGE. By Dr. Louis Julien (Paris), Surgeon of Saint-Lazare Prison. Translated by R. B. Douglas. Pages v-169. Extra Cloth, $1.00 net, Delivered. Philadelphia: F. A. Davis Company, Publishers. 1901.

TWENTIETH ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF NEW YORK. For the Year ending December 31, 1899. Transmitted to the Legislature February 15, 1900. Cloth. Pp. 555. Albany: James B. Lyon. 1901.

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF THE STATE OF ALABAMA. The State Board of Health, Organized 1847—Meeting of 1901. Selma, April 16-19. Cloth. Pp. 508. Montgomery, Ala.: Brown Printing Co. 1901.

THE PATHOLOGY AND TREATMENT OF SEXUAL IMPOTENCE. By Victor G. Vecki, M.D. Third Edition, Revised and Enlarged. 12mo. Cloth. Pp. 329. Price, $2.00. Philadelphia and London: W. B. Saunders & Co. 1901.

TRANSACTIONS OF THE MASSACHUSETTS MEDICO-LEGAL SOCIETY. Volume III—Number 3: 1901. Paper. Pp. 44. Boston: Published by the Society. 1901.

PROCEEDINGS OF THE NEW YORK PATHOLOGICAL SOCIETY. April, 1901. Paper. Pp. 44. Published by the Society.

MAPS ACCOMPANYING STATE BOARD OF HEALTH OF NEW YORK. Twentieth Annual Report for the Year 1899.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Sept. 26 to Oct. 2, 1901, inclusive:

Joseph L. Bell, contract surgeon, from Fort Morgan, Ala., to his home, Richmond, Ind., for annulment of contract.

Henry D. Belt, contract surgeon, leave of absence granted.

James Carroll, contract surgeon, former orders amended so as to direct him to return from Havana, Cuba, to his proper station in Washington, D. C., not later than Nov. 1, 1901.

Max F. Clausius, contract surgeon, on his arrival at Fort Douglas, Utah, to proceed to Fort Grant, Ariz., for post duty; but this order was revoked, and he was directed to proceed to his home, Burrington, Ill., for annulment of contract.

Marshall M. Cloud, lieutenant and asst.-surgeon, U. S. A., sick leave of absence extended.

Frederick A. Dale, lieutenant and asst.-surgeon, U. S. A., to proceed to San Francisco, Cal., for return transportation to Manila, P. I., in compliance with orders from the Division of the Philippines.

Robert C. Eve, contract surgeon, from Fort Freemont, S. C., to Augusta, Ga., for annulment of contract.

Samuel A. Greenwell, contract surgeon, from duty at Fort Clark, Tex., to his home, Cleburn, Tex., for annulment of contract.

Eugene H. Hartnet, lieutenant and asst.-surgeon, U. S. A., member of examining boards at Governor's Island, N. Y., Sept. 27 and 28.

T. G. Holmes, contract surgeon, leave of absence granted on the expiration of which he will proceed to San Francisco, Cal., for duty on the transport *Grant*.

Frederick E. Jenkins, contract surgeon, on his arrival at Fort Riley, Kan, with troops, will proceed to Fort Morgan, Ala., for post duty.

William P. Kendall, major and surgeon, U. S. A., member of a board at Buffalo, N. Y., to determine the physical fitness of certain persons for appointment as lieutenants in the Army.

William C. LeCompte, contract surgeon, member of a board at Buffalo, N. Y., to determine the physical fitness of certain persons for appointment as lieutenants in the army.

Frederick H. Morhart, captain and asst.-surgeon, Vols., honorably discharged from the service on account of disability.

Edward L. Munson, captain and asst.-surgeon, U. S. A., member of a board at Buffalo, N. Y., to determine the physical fitness of certain persons for appointment as lieutenants in the Army.

Paul Shillock, major and surgeon, U. S. A., now at San Francisco, Cal., to proceed to Fort Riley, Kan., for duty at that post.

J. Samuel White, contract surgeon, having arrived at Seattle, Wash., will proceed to Fort Assinniboine, Mont., for post duty.

Navy Changes.

Changes in the Medical Corps of the Navy, week ending Oct. 5, 1901:

Surgeon P. Leach, ordered to recruiting duty at Port Royal, S. C.

Surgeon P. Leach, order to recruiting duty at Port Royal, S. C., revoked.

Asst.-Surgeon E. J. Grow, order to proceed home, upon detachment from the *Castine*, modified; ordered to the New York Navy Yard.

Medical Director J. C. Ayers, detached from the Naval Hospital, Chelsea, Mass., October 15, and ordered home and to wait orders.

Medical Director D. Dickinson, detached from duty on medical examining board at Washington, D. C., October 10, and ordered to duty in charge of the Naval Hospital, Chelsea, Mass., October 13.

Surgeon S. H. Griffith, detached from duty at the Pan-American Exposition, Buffalo, N. Y., October 9, and ordered to duty as a member of the medical examining board, Washington, October 10.

Surgeon H. L. Law, retired, ordered to duty at Buffalo, N. Y., in charge of the exhibit of the Bureau of Medicine and Surgery, at the Pan-American Exposition, and as attending medical officer at the naval recruiting rendezvous, October 9.

Asst.-Surgeon D. B. Kerr, detached from the *Culgoa*, when put out of commission, and ordered home and to wait orders.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Sept. 28, 1901:

SMALLPOX—UNITED STATES.

California: San Francisco, Sept. 14-21, 1 case.
Indiana: Michigan City, Sept. 24-Oct. 1, 4 cases.
Kentucky, Lexington, Sept. 21-28, 1 case.
Massachusetts: Boston, Sept. 21-28, 2 cases, 1 death.
Michigan: Detroit, Sept. 22-29, 1 case.
Nebraska: Omaha, Sept. 14-21, 1 case.
New Jersey: Newark, Sept. 21-28, 6 cases, 5 deaths.
New York: Sept. 21-28, Elmira, 4 cases; New York, 5 cases, 2 deaths.
Pennsylvania: Philadelphia, Sept. 21-28, 29 cases, 3 deaths.
Ohio: Youngstown, Sept. 21-28, 1 case.
Utah: Salt Lake City, Sept. 14-28, 2 cases.
Washington: Tacoma, Sept. 15-22, 1 case.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Aug. 3-10, 1 case.

SMALLPOX—FOREIGN.

Austria: Budapest, Sept. 2-9, 2 cases.
Belgium: Antwerp, Sept. 7-14, 1 case, 1 death.
Brazil: Pernambuco, Aug. 8-15, 56 deaths; Rio de Janeiro, Aug. 4-18, 114 deaths.
Colombia: Panama, Sept. 16-23, 15 cases.
Great Britain: London, Aug. 24-Sept. 7, 166 cases, 15 deaths.
Italy: Naples, Sept. 7-14, 57 cases, 6 deaths.
Russia: Moscow, Sept. 7-14, 2 cases, 1 death.
Spain: Madrid, June 17-July 15, 6 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Aug. 3-10, 6 cases, 3 deaths.

PLAGUE—FOREIGN.

Australia: Brisbane, June 1-30, 3 deaths.
Brazil: Rio de Janeiro, Aug. 4-18, 5 deaths.
China: Canton, Aug. 5, diminishing.
Italy: Naples, Sept. 7-30, 15 cases, 4 deaths.

YELLOW FEVER.

Brazil: Pernambuco, Aug. 8-15, 1 death; Rio de Janeiro, Aug. 4-18, 2 deaths.
Cuba: Havana, Sept. 4-21, 3 cases, 2 deaths; Santiago, Sept. 20, 6 cases, 1 death.
Mexico: Vera Cruz, Sept. 14-21, 5 cases, 2 deaths.

CHOLERA.

Java: Batavia, Aug. 3-17, 5 cases, 3 deaths.

REMOVAL OF FOREIGN BODIES FROM THE AIR PASSAGES.*

DE FOREST WILLARD, M.D.
PHILADELPHIA.

The entrance of a foreign body into the larynx is at once the signal for violent expulsive efforts, and in the majority of instances voluntary extrusion is accomplished. Should the object, however, pass the vocal cords, the route to the bifurcation of the trachea is free and unobstructed. At the bifurcation, as the right bronchus is larger and turns at a less abrupt angle to reach the root of the lung, the body is more likely to fall into its lumen, although this result is by no means positive.† If the object is of irregular shape it will not closely fit, and violent efforts at coughing may still loosen it. It may, however, be arrested in its reverse course at the vocal cords. The violence of the efforts, and the interference with the air supply, unfortunately make inspiratory suction as sudden and nearly as intense as expiration, and the offending object may be sucked further into the air passages. The position of final fixation will depend upon these efforts and upon the size and character of the foreign body. The degree of air hunger will depend upon the amount of blockade. Should the entire main bronchus be obstructed, one-half the respiratory tract will be shut off and the dyspnea becomes extreme. Unfortunately, the physician is rarely at hand and immediate professional measures of relief can not be instituted. The majority of these accidents occur in children; consequently, it is well to instruct parents as to the procedures that should be adopted. The rule as ordinarily taught is to the effect that inversion of the child is unsafe, since the object may become blocked within the larynx. As the body has, however, entered by this route, and as it is the one that must be taken in any voluntary expulsion, it is probably the safest domestic practice that can be instituted and may prevent the object from being sucked still lower in the bronchus. An exaggerated prone Trendelenburg position may be maintained until the arrival of the surgeon. Succussion of the individual and vomiting have occasionally dislodged the body. Coughing should be encouraged, but the violence of inspiratory movements should be restricted as far as possible. Brodie reports the case of an adult in whom a half sovereign had reached the bifurcation of the trachea. By inversion of his body in the prone position, and succussion, he was able, after six weeks, to dislodge the offender by coughing, and full recovery ensued.

If the arrest has taken place at the vocal cords, a laryngoscopic examination will probably reveal it, and it may be extracted by forceps or by laryngotomy. In splitting the thyroid cartilage and opening the larynx, care should be taken to keep directly in the median line and to avoid injury of the arytenoid cartilages and muscles. Cocain should be applied to the mucous membrane both before and during the operation, to prevent reflex inhibitory influences upon the heart.

If an *x*-ray apparatus is at hand, and the foreign body is one which is impenetrable to these rays, as coins, nails, etc., the location may sometimes be accurately determined by making shadowgraphs at different angles. Unfortunately, the distress is so urgent and extreme that it is difficult to induce the child to remain quiet long enough to obtain such a shadow unless ether is administered; still, the *x*-ray representation fills a most important place in both acute and chronic blockades of the air passages.

With children, beads, beans, portions of whistles and toys are common intruders.[1] Hard bodies will probably imbed themselves and do not offer much opportunity of being seized by forceps. Vegetable substances are likely to swell from the moisture if they remain long *in situ*, and are, therefore, difficult to dislodge. In one of my fatal cases one-half of the brown shell of a chestnut was drawn far down into the subdivision of a bronchus.

It is important that the history should be reliable, and when a body has been swallowed, close investigation is necessary to determine whether the object has entered the air passages, and secondly, its location. Of course, there are many cases where the symptoms are unmistakable, but when in doubt a most careful diagnosis should be made. A young child not infrequently has a foreign body in its mouth; is seized with violent coughing as the body attempts to enter the larynx, and yet it passes into the stomach. Not a few tracheotomies have been performed in the search for such objects which have later been passed per rectum; consequently, it is unwise to operate in the absence of definite symptoms. Moreover, many a child has been apparently choked with a toy which was supposed to have been swallowed and which has ultimately been found in the corner of the nursery. I have myself witnessed in the practice of one of our most prominent surgeons, a tracheotomy with prolonged search, in which case the article which had supposedly been swallowed was later found in the pocket of the child, and an examination of the lungs (which should have been made previous to the operation, but which was instituted afterwards) developed the fact that the dyspneic symptoms were due to double pneumonia from ordinary causes.

Following impaction, the pain and the absence of respiratory movements will usually be found upon one

1. Poulet: Foreign Bodies, 1880, vol. II, p. 22.

side of the chest. The absence of vesicular murmur shows the interference to entrance of air, which will be followed later by dulness and signs of consolidation. In partial occlusion the respiration will be stridulous. The interpretation of these signs, taken in connection with other symptoms, must rest with the surgeon, but he must not be deceived by the lull in symptoms that not infrequently follows the initial blockade.

Tracheotomy.—The opening of the trachea is naturally the most frequent method for reaching an impacted foreign body, an operation that was advocated as early as 1644 by Frederic Manavius. Speedy relief is usually demanded, and ether or chloroform may be employed, or better, local anesthesia in order to retain the use of the extraordinary muscles of respiration. In doing this operation it is better to remove a considerable circle, excising one or two cartilaginous rings, since a simple slit may interfere with the expulsion of the body. If a slit only is made, lateral stitches holding it open are better than a tube. Not infrequently the foreign body is ejected by the primary cough induced by the operation; consequently it should be the duty of an assistant to watch carefully for its appearance. Fortunately, expulsion occurs in about one-half the cases operated upon. This result may be hastened by irritation with a feather. The opening should be as nearly as possible to the top of the sternum, and the forceps must be used with extreme care. The difficulties in locating the body with tracheotomy forceps depend largely upon its character. A bean or kernel is of the same consistency and feeling as the cartilaginous bifurcation of the trachea. If the object is known to be a soft vegetable one, ordinary serrated forceps will not hold. Very short needle-like teeth which will sink into and hold the substance are better. With beads, buttons, tin whistles, etc., successful removal becomes difficult, even when they can be grasped.

One familiar with the use of the cystoscope may, by throwing the head far back and to one side, obtain a view of the foreign body through an inserted tube with electric light. For hard objects a large soft-rubber tube attached to a Bigelow litholapaxy evacuator may be carried down the trachea, and strong suction made upon it, or an aspirating pump or rubber ball may be attached. The evacuator is better, however, lest the body once extracted be again sucked back into position. In case of tacks, nails, etc., a small magnet or an electrical probe may be inserted through the trachea. Blunt curettes, wire hooks, scoops, loops, etc., are occasionally useful. The dangers to the trachea and bronchi by prolonged instrumentation are very great and should never be continued more than a few minutes. The risks of pneumonia are so greatly increased by instrumentation that Weist,[2] in an analysis of 1674 cases, found that the dangers of death from this cause in unsuccessful cases fully counterbalanced the benefits obtained by the number of extractions by tracheotomy. The proportions are one death in three and one-half cases without operation; one in four with tracheotomy. His conclusions in regard to this subject will probably not be materially changed by our present methods, since, although the pneumonia is septic in its origin, yet the sepsis even in former cases was probably not due in large measure simply to the instruments, but to the traumatism to the bronchi. Experiments show that the entering air is septic in the larger bronchi, but aseptic in the smaller divisions.

2. Trans. Amer. Surg. Assoc., vol. i, 1883, p. 121.

Failing to secure the intruding object through the tracheal opening, the surgeon is compelled to face two problems, either of which means serious risk to life. Shall he abandon the case to the expulsive efforts of Nature? Shall he rely upon the fact that many such offending bodies have been coughed out even after many years of suffering, and even when the diagnosis of tuberculosis of the lung has seemed positive? In determining the question the surgeon will consider both the character of the foreign body and the amount of interference that it is giving to the air supply. In the case of seeds, etc., voluntary expulsion with subsequent recovery occurs in nearly 74 per cent. of cases.

The other alternative is to reach the bronchus by a direct route. Should the surgeon decide to invade the chest wall in an heroic effort to reach the bronchi, he has before him a series of manipulations, perils, and difficulties that will put to the extreme test his skill, coolness and judgment. Before the introduction of the artificial respiration apparatus, the profound and deadly collapse that immediately followed any invasion of a healthy chest, was sufficient to deter most operators from undertaking such a course. Quenu lost twelve out of fifteen dogs, and while my own experiments have not been quite so serious, they have been very discouraging. In these animals and in rabbits and goats, the communication between the two pleural cavities which exists just above the tendinous center of the diaphragm renders the entrance of air doubly dangerous. Fortunately, we are now better equipped and can confidently rely upon our artificial respiration methods, but without such accessories the conditions are appalling. The exceptional cases in which atelectasis does not occur are so few in number and are so unexplainable that they can not be depended upon. The surgeon must also consider the fact that even when the bronchus is reached by any route, the rigid walls prevent the easy recognition of the foreign body either by sight or touch. Again, as in Curtis' case, even when found in a secondary bronchus, it could not be reached or extracted. In experiments upon dogs I have repeatedly failed to find in the bronchi, pebbles that I had introduced through tracheotomy wounds.

Unfortunately, practice upon the cadaver yields but a slight realization of the conditions found in the living subject. I have at autopsy seen the bronchus of a dog apparently within easy reach, which same bronchus I had seen ten minutes before surrounded by huge pulmonary and azygos veins, with aorta, pneumogastric nerve, root of lung, and every structure in the neighborhood being violently dragged by the wide excursions of the lung in the frightful air hunger of the collapse from acute pneumothorax.

When an opening of any considerable size is made in the pleura and air rushes in, the sudden symptoms of collapse are usually instantaneous. The sudden shifting of the oxygenation of air upon one-half the ordinary circuit; the violent efforts of both inspiration and expiration; the enormous movement of the lung in the effort to produce a vacuum in the chest; the flapping of the pleura and mediastinum; the huge swelling veins filling and emptying and covering the area of operation; the great peril of the patient; the cyanosis and deficient oxygenation are such complications as will greatly delay and often entirely prevent all safe manipulative measures.

I have called attention to these difficulties, not to exaggerate them, nor to deter any surgeon from invading

the chest wall, but only to warn him against rash work without proper apparatus, since failure will necessarily bring discredit upon the surgeon and disaster to the individual. A somewhat extended but still incomplete examination of the literature on the subject fails to reveal a recovery after opening of the bronchus. My object is only to urge that unless an artificial respiration apparatus is at hand, and oxygen obtainable, it will be wiser to cease one's operative methods, after short manipulations through a large tracheal opening. With full appliances, however, and a full knowledge of the dangers, one may calmly proceed to enter the chest by a selected route. The conditions are entirely different from those encountered in a diseased lung or pleura, and preliminary injection of air or liquid will avail but little. A small dose of atropia will be helpful.

The oft-tried expedient of plugging the hole in the pleura, or of dragging the lung into the opening, or grasping the base of the lung, is here of no avail, since the search for the bronchus is absolutely prevented by any of these procedures. Air hunger being then the most serious of the complications, some reliable means of artificial respiration must be at hand, or the patient must die in a few moments. Fortunately, the Fell-O'Dwyer[3] apparatus gives us the much-needed help. The apparatus consists of intubation tubes of various sizes attached to a handle, by means of which one of them of proper size can be held permanently within the chink of the glottis, while air is pumped directly into the lungs by bellows worked by hand or foot pressure. Insufflation is accomplished by moderate pressure about fifteen times in the minute, while expiration is accomplished by the resiliency of the chest walls.

Matas has improved upon this apparatus by using a double pneumatic pump, by means of which the exact amount of air introduced can be measured. He has also attached a manometer to regulate the degree of pressure, and has added a branch tube through which anesthetization can be kept up. The entering air is also filtered through a cylinder filled with cotton. The pump can also be employed for forcible aspiration of air from the lung. Bloom, Doyen and others have altered these instruments, but the principle of forcibly supplying air is the same.

After tracheotomy the intubation tip can be introduced through the opening so as to fit the trachea, or it can be carried into the glottis and the wound closed.

A pressure equal to 6 mm. mercury has been found sufficient to dilate the lung, while too great pressure, as 33 mm., will interfere with respiration. If too great force is used, emphysema or air vesicle rupture may take place. The artificial movements should correspond as closely as possible to the normal respirations.

By the employment of such an appliance for carrying on respiration, the chest wall may be opened either anteriorly, posteriorly, or at the side. A large opening while much more dangerous as regards atelectasis, yet greatly facilitates the operation. The employment of a tiny electric bulb within the chest also adds greatly to the rapidity and safety of the manipulations.

Anterior Thoracotomy.—Milton, of Cairo,[4] has recommended an operation of entrance which he calls the normal thoracic invasion, and has successfully practiced it upon a living patient. In young children with flexible bones it would be feasible for reaching the bronchus.

With a saw he splits the sternum longitudinally throughout its entire length, and forcibly retracts the halves, thus separating the two pleural layers, and reaching the anterior mediastinum. In attempting this operation it should be remembered that the pleuræ come together not in the median line, but at a line nearly at the left border of the sternum. In this, as in all other routes of entrance to the thorax, it is absolutely essential that an efficient artificial respiration apparatus shall be constantly employed in the prevention of collapse.

Gaston's[5] anterior opening is made as follows: A quadrilateral trap-door flap is made to include the third, fourth, fifth and sixth ribs, and turned back upon its base at the costal cartilages, thus avoiding the internal mammary. The outer end of the square flap is at the mid-axillary line, and the entire chest walls are cut through with knife and saw.

In making an anterior thoracotomy[6] I have tried various forms of incision. The bronchus of the second lobe can be readily reached anteriorly, can be incised and afterwards stitched with a staphylorraphy needle. In another operation upon the right side, with excision of the fifth rib, I was easily able to expose the bronchus of the right upper lobe. The bronchial, pulmonary and a very high azygos vein were pushed aside and the bronchus incised for a third of an inch without wounding any other structure. Whenever the wound in the bronchus was not subsequently stitched, and the chest wall was closed at the end of the operation, each inspiratory act caused an increase of the pneumothorax by entrance of air through this slit, as was evidenced by the bulging of the wound and the increased dyspnea, ending in death.

The same thing occurred in another dog after an excision of the fifth rib, and an opening of the right bronchus. The pneumothorax steadily increased after the closure of the wound, with bulging and escape of air from within outward at each respiration until death occurred. It is easily seen that while air can pass from the interior of the bronchus outwardly, the rounded shape of the tube prevents return from pleural cavity to bronchus. This air from the large bronchi is septic.

Posterior Thoracotomy.—Nesiloff, Bryant and others have proposed to reach the root of the lung posteriorly. Bryant's operation is as follows:[7] In order to give room for the flap, the scapula is carried far outward by raising the arm and carrying the shoulder forward. A square flap three inches in size is made, with its base toward the spinal column, and three ribs, the third, fourth and fifth, are sawed through as far out as their angles, near the posterior border of the axilla. The pleura is then separated from the anterior surface of the ribs by the fingers, and the flap is turned backward upon its base as a hinge, the ribs being separately turned out. The intercostal arteries were ligated before opening the pleura. The presence of the vena azygos and the pulmonary vein will greatly interfere with manipulations, and these, as well as the pneumogastric, must be carefully avoided. If the foreign body can be located, a long incision (long enough to permit removal without laceration) is made in the bronchus. The bronchus is not closed, but packed and drained, as there will be discharge of mucus and inflammatory products. The flap with the ribs should be replaced, but the middle rib may be removed entirely for drainage, if advisable. Any

7. Bryant: Posterior Mediastinum. Trans. Amer. Surg. Assoc., vol. xiii, p. 443

given spinous process indicates the situation of the vertebral extremity of the rib immediately below. Bryant places the division line between the posterior mediastinum proper and the posterior part of the superior mediastinum at the lower portion of the fourth dorsal vertebra. The separation of the pleura is accomplished with the finger, and also by a sawing motion of a strong silk thread carried beneath the rib. The same ligature may be used to draw beneath the rib a chain saw, so as to operate from within outward and avoid premature wounding of the pleura. This opening is probably more favorable for reaching the esophagus than the bronchus. The bronchus in a man will be distant about one and one-half inches from the opening. The operation is one requiring careful manipulation, cool judgment, speedy recognition and skilful treatment of each danger as quickly as it arises.

Curtis,[8] in a posterior thoracotomy for an impacted seed vessel of a plant in the right bronchus, tried to extract it with a forceps through the trachea, but failed. At a second operation the boy was placed face downward, with one shoulder raised. A quadrangular flap was raised from the posterior portion of the chest and turned outwardly toward the scapula. Its free edge was near the vertebral spine. The fourth, fifth and sixth ribs were then stripped. The lower layer of the periosteum and intercostal muscles were divided without opening the pleura. The ribs being lifted up, the pleura was carefully detached from the posterior mediastinum and from the posterior chest wall. The bronchus was easily reached, but the azygos vein covering it prevented incision. He encountered the same difficulties that I have always experienced, the violent action of the lung and of the flapping pleura, which interfered most seriously with all manipulations, and he was finally obliged to pack the wound and suspend his efforts. The next day he renewed the attack. The pleura had now become adherent to the lung, and the action was less violent. The bronchus was opened through its posterior wall without hemorrhage, but search with forceps failed to find the body; neither could it be found in the trachea. It was finally discovered by the fingers through the lung substance. The pleura was sewed to the lung and the lung held by a silk stitch. The thermocautery was used directly through the lung substance, but failed to reach the object. The operation was finally suspended on account of the patient's collapse. A drainage tube was inserted with packing, but pneumonia developed on the following day and the patient died in forty-eight hours. At the autopsy the foreign body was found in the secondary bronchus near the end of the drainage tube. The object had been swallowed three days before the first operation. Rushmore[9] in a similar attempt anteriorly was compelled to abandon the operation, and the patient died.

Anyone interested in the subject of intralaryngeal insufflation will be abundantly repaid by perusing Matas' able articles.[10] In these papers he shows that insufflation through a deliberately introduced laryngeal tube was in common practice for the resuscitation of the drowned as far back as the War of the Revolution; that William Hunter used both bellows and intralaryngeal tubes; that Matas' present pump was forestalled by the double pump of Courtois attached to a tracheotomy canula, more than a century ago; that in the earliest years of the last century such a tube was a part of the regular obstetrical outfit for the resuscitation of new-born infants;[11] that Ribemont in 1877 used an intubation canula almost precisely like the one of O'Dwyer; that Truehead of Texas again in 1869 brought out an instrument upon the same plan as the Fell-O'Dwyer instrument.

The Bloom modification of attaching an ordinary rubber syringe bulb to the laryngeal tube is excellent, and the Doyen[12] double bellows and tubes are also good.

The work of Tuffier[13] and Hallion, Quenu and Longuet, Matas, Parham and others, has added greatly to the practical application of artificial forcible insufflation through an intralaryngeal tube. It is now the best known assistant, not only in the performance of lung surgery, but also in the resuscitation of the asphyxiated, the drowned and the new-born. It is also most serviceable in opium poisoning, and in the arrested respiration of anesthetization. (I always keep the Fell-O'Dwyer apparatus alongside the oxygen jar, close outside my clinic door.)

When the foreign body remains permanently fixed in the bronchus, septic pneumonia is a frequent result. In many cases this process leads on to septic abscess, or, if the blockade is complete, gangrene may result. Expulsion of the foreign body and of the purulent surrounding material sometimes occurs, often after months of delay. More frequently, however, death ensues. In the chronic cases the hemorrhage, emaciation and septic conditions often simulate tuberculosis. The proper treatment for all such abscesses or gangrenous areas of lung is a surgical one. The diseased area having been carefully located, a rib should be excised subperiosteally, and contamination of the pleural cavity prevented by suturing of the lung to the chest wall in the form of a parallelogram, before opening. A sharply curved perineal needle with handle is convenient for this purpose. Incision of the abscess and free drainage will offer the best hope for cure.

CONCLUSIONS.

1. Coughing should be encouraged; forcible inspiration restrained.
2. Inversion in the prone position as a domestic practice is advisable.
3. Laryngoscopy is helpful if the body is lodged at the vocal cords. It may be extracted by forceps or by laryngotomy.
4. If time permits, the *x*-ray may be brought into serviceable use for diagnosis.
5. Careful diagnostic investigation is important to determine the actual presence of an impacted body, and its location.
6. Tracheotomy under local anesthesia should be the rule if the object is lodged at the bifurcation or in the bronchi. Tracheoscopy, suction and forceps' manipulation must be cautiously employed. Prolonged instrumentation adds greatly to the danger of pneumonia.
7. If extraction is not secured through the tracheotomy wound the chest wall should not be invaded unless an artificial respiratory apparatus like the Fell-O'Dwyer is at hand, and oxygen available. With the assistance of these appliances, however, the bronchus may be reached, anteriorly or posteriorly, since, by their use, rhythmical movements can be maintained.
8. Resultant abscess of the lung should be treated by incision and drainage.

THE TREATMENT OF EMPYEMA.*

JAMES H. DUNN, M.D.
PROFESSOR OF SURGERY IN THE UNIVERSITY OF MINNESOTA.
MINNEAPOLIS, MINN.

The average treatment of empyema is still far from satisfactory and decidedly behind the present state of surgical science. Tardy diagnosis, inefficient drainage and slovenly after-treatment are the most frequent causes of failure, retarded convalescence and great deformity, results which, though much less frequent than formerly, are not seldom encountered at this late day. The operative treatment of the disease is too often undertaken by those unfamiliar with modern surgical methods. It is high time that a greater respect for the chest should be impressed upon practitioners who appear to regard the treatment of pleural suppurations lightly, and as a fair field for any one able to insert a tube and diligently use a syringe.

The rational treatment of suppurating pleurisies is simple and well known to competent surgeons. Early diagnosis, prompt and efficient drainage, and aseptic after-treatment summarize the whole matter. It is only in the details of technique that discussion is likely to arise and further improvement in methods is to be sought.

EARLY DIAGNOSIS.

Prompt recognition and adequate drainage of the purulent effusion minimizes ruptures into bronchi, systemic infection, loss of lung expansion and pleural thickening. The degree to which the collapsed lung recovers itself depends largely upon the density of the visceral pleura and upon the length of time during which the lung has been compressed. Pulmonic sclerosis and pleural thickening are the chief causes of difficulty in obliterating these cavities. Hence, while there are other causes of tardy or imperfect lung expansion, late diagnosis is one of the most serious and frequent, and one which very moderate skill and diligence ought to almost wholly remove. Perhaps the most excusable delay occurs in certain empyemas developing with or closely following pneumonia, but the abnormal course of events should sufficiently arouse the attendant's suspicions to lead to the use of the exploring needle before many days have passed, even in the most deceptive cases. In any case of thoracic dulness open to doubt, so safe, certain and easy a means of diagnosis as aseptic needling should not long be delayed.

Having early recognized the presence of a suppurating pleurisy, by the needle, a bacterial diagnosis of the variety of the infection is exceedingly desirable. However, pleural suppurations are in practice so generally due to mixed or virulent infections, that serious errors in treatment are not likely to follow its omission in the hands of experienced clinicians to whom the physical properties of the exudate are ordinarily sufficiently characteristic for practical purposes.

EFFICIENT DRAINAGE.

A pleural suppuration being recognized, all the world has agreed that it should be removed; but how and where, have been much discussed. Before the era of aseptic surgery and bacteriology a great variety of methods were alternately used, abandoned and resumed. Puncture with the trochar, aspiration, intercostal incision, puncture and injection of antiseptics, continuous irrigation, etc., were alternately lauded and rejected. Ingenious tubes, complicated instruments and theoretical appliances were proposed. Indeed, the practical surgeon must still be astounded at the antiquated assertions and loose advice still prevalent in many textbooks. At present we know there are empyemas and empyemas. Certain benign infections are easily cured by means wholly inefficient in others. In our present light the indications for rational treatment appear to be clear and fairly definitely established. A very few yield to paracentesis, and a certain other few are, perhaps, best treated expectantly so far as operation is concerned. It is also well known that certain benign effusions may be successfully drained by simple intercostal incision without rib resection, especially in children, and yet this operation is rarely advisable. Thus, the normal procedure for acute empyema is thoracotomy with resection of a rib. This should be the rule, because it alone is adequate to the best treatment of the vast majority of cases, and because skilfully done it is scarcely more difficult or dangerous *per se* than the less efficient drainage of simple intercostal incision.

The drainage opening should be large enough to allow of the removal of all clots and débris, to admit of careful examination of the cavity, even in some cases to allow of inspection by reflected light, and to remain thoroughly open until the cavity under ordinary circumstances may be expected to close. To these ends it is well to resect 6 centimeters of a rib, which admits of the introduction of three fingers. Personally, in certain cases where the conditions found indicate that a very prolonged drainage will be necessary, I occasionally resect two ribs, simply with the idea of establishing a lasting free drainage and keeping the cavity under inspection during its closure. This is, of course, unnecessary in simple acute cases. In my experience, especially in the past, the drainage opening is made too small ten times where it is once made unnecessarily large. The difference in traumatism between making a small opening and one admitting three fingers and giving full command of the cavity is little, but the difference in efficiency is great. I would make three exceptions to this rule of rib resection as the normal procedure in acute empyemas:

1. In pure pneumococcic pleurisies, thoracentesis may be tried, and it not rarely succeeds. This variety is more frequent in childhood—hence, the frequently reported cases by aspiration and small drainage in children. This fact, together with the greater intercostal space in these subjects, has led to a disposition to view the indications for treatment of empyema in children as differing from that of adults, a contention without much foundation, and unless it be in very young infants, rib resection should be the rule. I have met with only two cases of pure pneumococcic pleurisy in adults. In one, a young man, a single aspiration of three pints of a light white pus was followed by prompt and complete cure. When the history of the case and the appearance of the exudate point to a probable pure pneumococcic infection, drainage should be delayed, and if bacterial examination confirms the suspicion, even a second, possibly a third evacuation by the aspirator may be tried before opening the chest.

2. There are certain pure tuberculous pleurisies in which drainage should be delayed until the advent of mixed infection. Tuberculous pleurisies are for the most part serous, until mixed infection occurs, when, as a rule, they are more or less benefited by free drainage. However, there are several varieties of tubercu-

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker and A. J. Ochsner

lous pleurisies as well as suppurating pleurisies in tuberculous patients, and it is a matter of good judgment rather than of set rules when to operate and when not. Briefly stated, I think the rule should be when the exudate withdrawn by the exploring needle is apparently sterile, or when there is little rise of temperature or evidence of sepsis, it should be left alone, or at most reduced somewhat from time to time by aspiration in case subjective symptoms arise, or the accumulation is increasing. This is especially the case in hemorrhagic tubercular effusions.

3. In large and double effusions, gradual evacuation by paracentesis is advisable as a preliminary measure, the rib resection being delayed a few hours. Or in double empyemas the rib resection may be made on one side and the siphon drainage of Bülau may be simultaneously instituted on the other.

ANESTHESIA.

In most cases the brief and light chloroform narcosis required for a rib resection is well borne, but if the general or cardiac conditions seem to contra-indicate chloroform, the operation, if dexterously performed, may be made with but little discomfort under local anesthesia (Schleich). Ether should not be used.

In operating under general anesthesia, the position on the table is of importance. In large effusions, and in cases which have already ruptured into a bronchus, the patient ought not to be placed upon the sound side; hence, a high table with the involved side drawn well over the edge, aids greatly in making a well-placed drainage.

As to the technique of the very simple operation of rib resection, there is but one point that occurs to me worth mentioning. Good bone forceps are undoubtedly the most handy instruments for section of the bone, but they sometimes disagreeably crush and fissure the rib. A much neater and smoother section is made by a Gigli's wire saw. Possibly the occasional neuralgias and some other rare sequelæ of rib resection might be avoided by this certainly more elegant method of resection.

LOCATION OF THE DRAINAGE.

In draining the pleural cavity the opening should be placed at the lower and posterior part of the collection, or rather at the point which is to become such as the cavity shrinks. Leaving out of consideration interlobular and supra-diaphragmatic collections, intra-pleural effusions vary considerably in their location in different cases, hence to place the drainage opening at any set place on the chest is manifestly absurd. It is doubtless a fact that purulent effusions most frequently occupy the lower and posterior portion of the pleural cavity; hence, in the majority of cases of empyema, the eighth rib, well back, just outside the angle of the scapula, is best chosen.

In the mid-axillary line and anterior to it the muscular covering is less thick than upon the latero-posterior aspect of the chest, and this naturally inclines the operator to choose a location which is often ill-placed. The usual dorsal position of the patient on the operating table further increases the difficulty of operating posterior to the mid-axillary line. An opening in this plane is quite sufficient for certain empyemas, but if the case is a bad one, i. e., a virulent infection, and the cavity large, I have often observed that the residual cavity, after a few days or weeks of drainage, is most often found to be upward and backward from openings placed low and forward. Hence, in most cases, a drainage placed moderately low and well posteriorly upon the unevacuated cavity proves most satisfactory during the latter course of the treatment. Indeed, in certain cases, the rib is best resected as far back as the angle. In at least three cases I have observed moderate-sized cavities located upwards and backwards under the scapula which could only be drained by such posterior-lateral incisions. In many cases drained by others or by myself, I have found after a short time that the opening came to be situated below and in front of the cavity, leading to the necessity of reopening further backward and upward. The rule ought to be to place the opening moderately low and well posteriorly upon the cavity. If it be too low, the diaphragm in certain cases soon rises over it and the drainage is soon imperfect and troublesome. I have never seen it placed too far backwards for the best results, but many times too far forwards. However, as a high posterior rib resection is a rather more formidable operation in certain cases, it is well to resect the eighth rib in the mid-axillary line as a primary measure, and some weeks later, if necessary, make a second higher and more posterior resection if required.

OF IRRIGATIONS.

After resecting the rib, the first opening through the pleura should be small so that a large part of the effusion may drain away slowly. When this has taken place the pleural incision is increased correspondingly to the piece of rib removed. Through this copious opening the cavity may be thoroughly cleansed by wiping out with bits of gauze on a long forceps. In case the condition of the patient demands it, this may be deferred to a subsequent time. Immediate irrigation of the cavity is often objectionable and always less efficacious than wiping out with gauze. In my opinion lavage of these cavities has a very limited field of usefulness. Two things are quite clear: 1, with the chest opened as freely as here indicated, frequent irrigations are not necessary; 2, the injection of empyemic cavities through small openings is decidedly dangerous. Sudden deaths, syncope, embolism, paralysis, various nervous phenomena, etc., which have been long observed and much discussed, are undoubtedly the most striking, but not the most frequent accidents of irrigation. Rises of temperature and various septic phenomena and complications very frequently follow too diligent lavage of these cavities. The smaller the opening and the more forcible the injection, the greater the liability to these various accidents. I have never seen any serious accident follow the gentle lavage of freely opened cavities, but I have come to believe that they do better with a minimum of irrigating. The idea of stamping out infection by the use of antiseptic washes is no longer rational. A few days after the free opening of a cavity peroxid may occasionally be poured over its walls or applied with a swab of cotton, or it may be washed out with warm bland solution if desired. The indications usually given for lavage are: 1, abundant purulent secretion; 2, fetid secretion; 3, if the fever persists or reappears after a period of apyrexia. It may surely be debated whether lavage avails anything against either of these indications. I am certain that it is a frequent cause of the latter condition, i. e., persistence or reappearance of the fever, and I have repeatedly known the temperature to subside when lavage was stopped. When a cavity can not be kept clean without much lavage, it usually needs to be reopened more freely. It is better to devote greater

care to external cleansing of the wound and skin, and to the occlusion dressing and less to the diligent squirting of quarts of fluid into these cavities. When the secretions increase or become foul, the cavity ceases to shrink, and the opening has become small, free reopening is usually followed by general and local improvement, whereas the most diligent syringing shows little if any beneficial results.

DRAINAGE TUBES.

With a large opening of the chest the chief object of the drain is to keep the wound from closing. When the bottom has been taken out of the reservoir, draining away of the secretion can scarcely be prevented. With a small hole entering the cavity at some point on its external wall, often with clots and débris retained, it can scarcely be kept clean with an irritating drainage tube. For the purpose of keeping the wound open and its lips in a good healthy condition, copious gauze drainage is preferable in most cases, at least in the early after-treatment. When the amount of secretion is great, rubber tubes surrounded by gauze may be preferable. There are many objections to exclusively tube drainage in these cases: 1. The wound is encouraged to close down rapidly and the command over the cavity by direct inspection is lost. 2. The pressure of the tube exercises a bad influence on the soft tissues. The tract occupied by a tube is usually in an unhealthy condition, in marked contrast to that of a large wound held open by sterile and iodoform gauze. There are doubtless stages and conditions in the course of the treatment of empyemas in which tubes are very useful, but I find myself using them less and less. When desirable, two large soft-rubber tubes placed side by side may be used. They should be of the size of the thumb, short, and not press upon the pleura. Great care is necessary in their daily sterilization, and some contrivance to secure against their loss in the chest must be instituted. When small openings were in vogue, nearly half the cases coming under my observation were found to have lost tubes in the chest. The many ingeniously devised drainage tubes are absolutely superfluous, to say the least. Valvular drainage tubes, as proposed by Williams and others, with the idea of expanding the lung during inspiration, are certainly not necessary and of doubtful efficiency. In empyema when the chest is opened the collapsed organ is expanded by air from the sound lung during expiration and in coughing. And this force is apparently much more effective than inspiratory efforts with the chest closed by a valve. If tubes are to be used for chest drainage none are better than those manufactured on the spot from sterile pure soft-rubber tubing, but personally I prefer gauze drainage for the most part and use tube drainage only in stages and cases where it seems more expedient. Many cases may be drained all through by gauze. More frequently after a time, when the cavity has become small, tubes are substituted with advantage. At times it is necessary to drain a considerable cavity through a small opening on account of the condition of the patient, in which case tubes are quite indispensable, but as a rule such a cavity needs a freer opening.

DRESSINGS AND AFTER-CARE.

The dressing of empyema cases is often very careless. These patients being ambulant most of the time, are often allowed to shift for themselves, and the after-treatment is anything but aseptic. Strictly speaking, a careful aseptic occlusion dressing ought to be maintained throughout the treatment from the first opening to the closure of the cavity. How rarely this is achieved we all know. While the dangers of seriously reinfecting an old granulating cavity are not great, such accidents may often be observed in the most chronic cases and doubtless sometimes occur in the early stages of acute cases, when a comparatively benign infection is rendered more virulent by the entrance of infection from without. Patients and attendants should be more impressed with the necessity for a rigid aseptic after-treatment of these cases. While the discharge is free the dressings should be changed as often as they become saturated, and during the whole after-treatment at least once a day.

Besides the general attention directed to the constitution and the local care of the wound, a third matter ought to receive constant consideration, viz., the progress of the expansion of the collapsed lung. During the early days of the after-treatment, cough tends to this end; hence, it should not be too far subdued by narcotics. If, after the patient has had time to recuperate, it is found that the lung is slow in expanding, means should be instituted to assist it. Until the cavity has nearly closed, forced expiration is the most efficient and practical means at our disposal, and the patient should be instructed in methodical forced expiratory movements with closed glottis. The suggestion of Koenig to require such patients to blow up air pillows several times daily is practical.

THE PROGNOSIS.

The prognosis as regards life naturally depends upon the nature and extent of the infection, and the resistance of the individual. As regards closure of the cavity, it may be said, I think, that acute empyemas, promptly recognized, freely and adequately drained, and aseptically treated, as a rule close in from three to twelve weeks. As the treatment of empyema becomes more rational, thorough and scientific, incurable fistulæ and cavities become more rare; in fact, the exception.

CHRONIC EMPYEMA.

However, some cases for various reasons become chronic, and the cavities are closed only with difficulty and after months of invalidism, and the performance of more or less extensive plastic operations. In a few, owing to feeble general health or tuberculosis, the final closure of a small sinus may be indefinitely postponed. Plastic operations should not be undertaken until the cavity has been reduced as far as possible by free drainage, general improvement of health and respiratory gymnastics. It is usually several months from the time of the primary opening before shrinkage of the cavity comes to an absolute standstill, when, if the general state warrants, thoracoplasty may be undertaken. When after long drainage the lung has expanded to the fullest extent possible, the mediastinum has been displaced, the diaphragm has risen, and the chest wall has fallen in until the ribs are in contact and a cavity or sinus still remains, it is evident that some other principle than drainage must be called into action if the cavity is to be finally closed. The idea of the surgeons who first attempted to close these chronic cavities seems to have been that closure is chiefly prevented by the rigidity of the ribs; hence, Estlander in 1877 proposed to mobilize the thoracic wall by resecting that portion of the ribs covering the cavity. In practice the cause of failure of most of these cavities to close is to be found rather in the pleura than in the ribs. The walls of these persistent cavities and fistulæ become indolent and quite

analogous to the edges of certain old indolent ulcers, and removal of the superimposed ribs alone rarely proves entirely successful in their complete closure. Hence, this type of thoracoplasty has been superseded by the Schede type of operation, in which the whole chest wall, save the skin, is removed over the cavity. Of late years cases requiring extensive plastic operations are much less frequent than ten or fifteen years ago, but in five cases during the past six years I have found it necessary to remove more or less extensive portions of the chest wall, and secured complete and prompt closure in such instance, whereas ten or fifteen years ago a much larger number of operations of the Estlander type were observed, in the majority of which sinuses remained as long as the cases were followed. Thus, with prompt and efficient treatment of acute empyemas, chronic cavities and fistulæ are rare, and these may with few exceptions be closed fairly promptly by thoracoplasty. When the general state is very feeble, when amyloid disease is advanced, when the cavity is enormous, failure is probable, but there are few absolute contra-indications to a well-timed attempt to close these chronic cavities. Tuberculosis is unfavorable, but by no means an absolute contra-indication.

DISCUSSION ON PAPERS OF DRS. WILLARD AND DUNN.

DR. A. C. BERNAYS, St. Louis—Pneumotomy and pneumectomy are the operations which deal with tuberculosis—first and last and all the time with tuberculosis, excepting, perhaps, a few cases where a surgeon would be called early enough to render aid in a traumatism from a gunshot wound or a stab in the chest. We are gradually encroaching on the domain of the medical men so much that soon our fellows may not have their lungs left. I really believe the time is at hand when we are going to attack the ravages of tuberculosis in the lungs with our surgical technic, and I believe we are going to do it successfully in many cases. In order not to discourage our efforts, we should carefully select suitable cases. It is a fact that pure infection by tubercle can recover spontaneously or by means of dietetic and climatic treatment. We all know that to be a fact, because we have all examined the sputa of tubercular patients and have seen them recover from dietetic and climatic treatment. In those cases prognosis is favorable as long as there is no mixed infection. As long as the patient has only the growth of tubercular bacilli in his lungs he may recover spontaneously, but in most cases there will soon be a mixed infection; that is what kills and that is what I think we can attack surgically. When there has been a secondary infection of the tuberculous patient by staphylococcus, streptococcus, colon bacillus, and other pathogenic microbes, or some of the saprophytic microbes, then our treatment must aim at their exclusion. Cavities in the lung are the points of attack. In considering their treatment, the question is simply this: Is the danger of the operation less than the expected benefit? Then the procedure is justified even if it is not a radical treatment. We must select cases that are not beyond the stage where recuperation is possible, just as we do in carcinoma. Cases in which a cavity in the lungs is the most prominent danger are rare, but if we can only bring one in a hundred of these unfortunates back to health, the operation of pneumotomy must appear as a justifiable operation. Just before I came here I had the superintendent of a public hospital send for me to see ten cases of death from consumption and in those ten cases I, with the aid of my assistants, went to the dead house and removed all of the soft parts over the top of the lungs on both sides, removing the whole clavicle, the first, second, and third ribs and then examined the tops of both lungs; the most interesting thing I found was that I could peel out with an elevator and with my fingers, the apices of the lung on both sides in eight out of ten cases without causing the pneumothorax. It was possible, by a blunt instrument, and with the fingers to peel out the upper part of the lung, in eight out of ten cases so that the lower part of the pleural cavity was not opened and there was no chance of producing a pneumothorax. While I was doing that post-mortem work, of course I had in view an operation which I could do upon a living patient and I believe that the best operation to be done in a case of that kind will be the following: Make an incision, beginning at the margin of the sternum and running through the pectoralis major muscle 5½ inches laterally in a straight line down to the second rib. Some French surgeons have advised making an incision over the first rib, but I think that is a mistake. The incision over the second rib gives much more room and is easier done. By means of the finger or a blunt instrument the pectoralis major muscle and soft parts are scraped off the ribs upwards and downwards. Then, by putting in a broad retractor, such as we use in the abdominal cavity in each side, the edges can be spread out and the second rib exposed for 5 inches. Another retractor placed into the lateral edge of the wound, will rest upon the axillary vessels and brachial plexus, but it will completely protect them so that, with the greatest ease, the second rib can be resected. I note that whenever I made a cut through the cartilage, the rib would stand out and then it is only necessary to use the wire saw or bone forceps, or even only to pull upon the medial end until it breaks off near its angle. All you have to do is to take hold of the second rib and break it off; it will break at its weakest point near the axillary line. It is not necessary to use bone forceps, but the second rib is taken hold of firmly and broken off, leaving not a ragged, but always a transverse break. You will have before you the white, almost bloodless, cicatricial-looking fibrous layer of tissue, the two layers of pleura having adhered, and you will find it not only difficult but requiring force with your fingers to loosen the cupola—the apex of the lung—out of its adhesions. Having loosened it clear around behind, on the sides and in front, then the finger will easily detect the fluctuation of the cavity; this cavity I would not open with the Pacquelin cautery, but with a knife. There is little danger of hemorrhage in the peripheral part of the lung. The top part particularly is not supplied with large arteries. The blood in them is under a low pressure and you can push your knife, or if you please, if you are in the tentative stage of surgery, you can push a thick trocar in there until you find the pus cavity. Having found the pus cavity, it should be opened by the method of Mr. Hilton. You remember he gave a method for the general practitioner to open abscesses, a method which avoids hemorrhage. After making the cut, press the dressing forceps into the cut, and enlarge the opening by separating the handles of the dressing forceps. In that way the abscess cavity can be widely opened and can be treated in any way that the operator may choose. In these cases that I examined very carefully I found that on the inside of the cavity you could see large blood vessels covered merely by a little pyogenic membrane, ready to burst. I found this in all the cavities I opened. Whether it would be well to tie those vessels with catgut or silk, I do not know. In this department of surgery we depend largely upon our theoretical studies. It would be a perfectly safe operation if in such a case as that you did not produce a pneumothorax but succeeded in getting into a cavity, to treat that part of the human body exactly as you would treat a case of pyonephrosis, appendiceal abscess, or abscess of the liver. The fever is caused by the pus, not by the tubercle bacilli, but by the secondary infection with pyogenic bacteria. You can drain the cavities and the patient's temperature will become normal rapidly. If he has a cavity also on the other side, it will not become normal until you open the other side. Dr. Willard covered the ground of treatment of foreign bodies in the air passages completely.

The first and important statement Dr. Dunn made was that the treatment of empyema depends upon microscopic findings in the fluid that have been brought out by the exploring needle. The condition demands that a microscopic examination must be made and the treatment must be governed by the findings of what is withdrawn with the exploring needle. One point that I never heard before was the use of the wire saw for the

purpose of cutting out the ribs. I shall undoubtedly adopt that plan, for that will prevent ragged and jagged edges. In regard to irrigation, I find myself absolutely in agreement and will only mention it in order to emphasize my position. I used to be a great irrigator, but I have absolutely abandoned irrigation, both in empyema cases and abscess of the liver, or in appendiceal or pelvic abscesses of any kind. It is a principle of surgery that where we have complete and free drainage we don't need irrigation. After drainage of an abscess, if fever arises, you can not cure that fever permanently by irrigation. What is indicated is to make the hole larger or make another hole in another place.

Dr. J. H. Barbat, San Francisco—I have been experimenting on dogs during the past year in the endeavor to solve some of the problems in thoracic surgery. I was unable to obtain any of the insufflation apparatus, and so had one constructed, which worked very successfully. It consists of a bellows with a spring, which can be adjusted so as to regulate the amount of air in each insufflation. The air is passed through a wash bottle containing hot water, so as to remove all dust and also warm it, thereby lessening the possibility of irritating the bronchial mucous membrane. A second bottle is provided with a two-way cock, which allows us to pass the air from the bellows either direct to the lungs, or to pass it through chloroform or ether, thus regulating the amount of anesthetic perfectly. I found in my experiments that it was easier in the dog to use a tracheotomy tube than an O'Dwyer tube. By anesthetizing the dog first, the tracheotomy tube was easily introduced, and then the insufflation and anesthetic could be kept up during the operation with comparative ease. To enter the chest cavity I make an osteoplastic flap by cutting through the requisite number of ribs near their attachment to the costal cartilages with a modified gardener's pruning shear, the cutting blade of which is thin and sharp, thus avoiding crushing the ribs. The next step consists in passing a full curved needle armed with heavy silk through the skin and around the rib, being careful to avoid including the intercostal vessels and nerve, at a point three or four inches back of the first cut. A Gigli-Haertel saw is then pulled through by means of the silk, and with two or three strokes of the saw the rib is weakened. All the ribs previously cut being treated in the same way, it is easy to turn back a large flap, without having seriously interfered with the circulation, which allows us to work with freedom on the contents of the chest cavity. In resecting the lung the electrohemostatic forceps of Skene may be used instead of the angiotribe, the only disadvantage being that it is necessary to carry the electrical apparatus with you while the angiotribe is complete in itself. In resecting a rib for empyema, time is an important factor, and I have found that the operation may be expedited by using Doyen's periosteotome, which consists of a piece of narrow half-round steel, one end of which is bent in the shape of the letter C and set at right angles to the shank. After cutting through the soft parts and periosteum with one stroke of the knife, the free end of the periosteotome is passed under the periosteum and worked up over the top of the rib, then down behind, avoiding the vessels and nerve, then out in front of the lower border of the rib. The shape of the instrument is such that when it is in position it fits the rib closely and all that is necessary to do is to move it back and forth a few times to loosen the periosteum perfectly, then with the sharp cutting shears the rib is divided, and the whole operation completed in from three to five minutes.

Dr. W. Jepson, Sioux City—In connection with the subject presented by Dr. Willard, I believe that there are few subjects in the whole domain of surgery where it is so essential that a clear conception should exist regarding what to do and how to do it, as when treating foreign bodies in the air passages. The statistics as collected by Gross, Weist and others, indicate that about 24 per cent. die when not operated upon. This is certainly a large mortality and must place this condition among the graver accidents; however, the saddest fact revealed by statistics covering a large number of cases is that more die when operated on than when not. Thus, of 1000 cases collected by Weist in 1878 or 1880, it is shown that the mortality was increased 4 per cent. by the employment of operative measures for the removal of the foreign body. Notwithstanding the sad results of operative interference in these cases, I say that Gross uttered an axiom when he, some forty-five years ago, stated that when a foreign body existed in the air passages, the trachea should be opened to facilitate its removal. This opinion was based upon his own personal experience, which showed that 17 per cent. more recovered when operated upon than when left alone. From a personal experience of 16 cases, 15 of which were operated upon with recovery in each instance, I advocate that, with few exceptions, where a foreign body has gained access to the trachea or bronchi, the trachea should be opened as soon as possible to facilitate its removal. It was said that the symptoms were often indefinite and vague. How true this is we quickly learn after even a limited experience with these cases; the phenomena occasioned by their presence may simulate those occasioned by any of the various affections of the respiratory tract, and it therefore behooves us not to overlook their presence. I seriously doubt if the employment of emetics, sternutaments, or inverting the patient and slapping upon the back, or other measures calculated to increase the expiratory force with a view of dislodging and expelling the body, are proper measures to employ. I recognize that now and then it may possibly be fruitful of the object aimed at, yet how often does it not fail and possibly with dire results. The upper third of the larynx is supplied by the superior laryngeal nerve, irritation of which may, through its relationship with vagus, lead to cardiac and respiratory inhibition, which may be most serious. We see this fact unconsciously recognized on the part of parents of children having seeds of corn, etc., in their air passages, by maintaining them in an upright posture so that the gravity of the foreign body keeps it out of the larynx, thus avoiding those violent attacks of coughing and choking.

The question of greatest importance pertains to the procedure of removing the foreign body after the trachea is opened. Foreign bodies in the air passages may be divided into two classes: 1, those which are movable within the lumen of the trachea or bronchi, bodies which are generally possessed of a more or less smooth surface, as seeds of corn, beans, coffee beans, etc.; 2, those which have become fixed in some part of the air passages, bodies which are generally irregular in shape, as tacks, pins, sand-burs, etc. Of course, a smooth body may become impacted in the larynx or either of the bronchi. After opening the trachea we readily recognize by the character of the breathing as to whether the body is distal or proximal, and are thus guided. If in the larynx, its removal can generally readily be accomplished by a suitable pair of forceps. If the body is located in the lower part of the trachea or a bronchus, especially if the same be hard and smooth as in the instance of many seeds, I doubt if we are warranted in making any attempt to grasp such a body with any forceps which we now possess. We would be much more likely to force it on down into the constantly diminishing lumen of a bronchi and thus impact it, making its subsequent removal very difficult if not impossible. The resistance offered by the trachea or bronchus to smooth bodies is not great until they are impacted, but it is necessary to grasp these bodies. All that it is necessary to do is to loosen them if impacted, when the expiratory current of air will carry them to the tracheal opening, and, if the trachea be slightly angulated by means of a pair of catch forceps or a loop of thread in each edge of the tracheal wound, the body will be ejected, or brought to the wound where it may be readily grasped. To loosen such bodies when fixed or impacted, no more efficient means can be employed, with possibly few exceptions, than that simple expedient of taking two or three strands of fine steel wire and twisting them together, leaving loops which may be passed beyond the object to loosen it on the withdrawal of the loops. A wire with a hook on its end and a half-circle higher up to keep the hook in the lumen of the passage, may at times be used to much advantage. No doubt the coughing excited

by the passing of the wire loops is a potent factor in many instances in loosening the foreign body. I concur in the view expressed by Dr. Willard that the simple opening of the trachea can not add to the risks of the patient; therefore, the large mortality in these cases, as shown by statistics quoted, must be due to other causes; probably because operative procedures were instituted too late or unwarranted instrumentation was employed and injury resulted.

DR. JACOB FRANK, Chicago—I have had considerable experience with two unpublished cases of lung surgery, and I have found from these and from experiments on dogs, that lung surgery is not so easy as most speakers would lead us to believe, with the exception of Dr. Willard. The first case was that of an abscess in the upper part of the right lung. I should say that it was an abscess of the lung, because the patient under anesthesia had frothy blood coming from his mouth. That is one of the signs and also one of the dangers in operations on the lung which has not been mentioned here, that is, drowning of the patient in his own blood. I worked my way down to it by resecting the clavicle and part of the first rib before coming to the abscess. This patient made a recovery. We introduced a syringe with a catheter, made suction, and the patient recovered. The second case that I had was that of a little boy who periodically would vomit from a quarter to a half a glass of pus. It could be distinctly determined on percussion when the abscess cavity was full and when it was empty. I thought it best to operate when the abscess cavity was full, but unfortunately when he was taking the anesthesia he vomited the pus. I resected the ribs and poked around with a needle twenty or thirty times until the blood came out of the boy's mouth and he was almost suffocated. I had the cavity soon cleared of the blood, and then worked my way with an artery forceps to find the cavity, and I failed. I am sure that I made enough laceration of the lung to find it, and can not say why I failed. The boy died. In lung surgery we stand to-day where surgery did twenty years ago in tuberculosis of the joints, first the resections and then afterwards getting to the curettement. I can not see the benefit of resection or excising any portion of a tubercular lung, unless we are sure there are not any tubercles a quarter or an eighth of an inch just beyond the border of the removed part, and I do not think that surgery of the lungs will ever become prominent—that is, excision for tuberculosis—unless we have some means to determine that there are no tubercles in any other part of the lungs. There is a difference whether we have a deep abscess of the lung to operate on without any adhesions of the pleura and the chest walls, or whether it is superficial. Merely an abscess, where there are adhesions already, is not more difficult to open than any other abscess.

DR. LEMOYNE WILLS, Los Angeles—There is much opposition to anything in the way of draining superficial cavities, or any operating on the chest until it is too late to do good. It is for the profession to overcome that opposition and not to allow their patients to go on in a septic, dying condition and then send them away to Arizona and New Mexico and Southern California, allowing the responsibility to be shifted to other men's shoulders and obliging the latter to sign the death certificate. That is the condition in which we get them. If you would diagnose your cases properly, treat them properly, as in operations on the brain and abdominal cavity, there would be more cases cured and fewer suffering consumptives in the last stages sent West to die. I am agreed with Dr. Frank that this is a matter of diagnosis. It is a matter of great care in the selection of your cases, but if you have a case almost moribund, with tubercle bacilli in sputum and a single large cavity in the posterior lower lobe, and can drain it, and if the man gets well and goes back to active life at his trade and puts on 75 pounds of flesh, that is certainly hopeful for the future of such operative treatment. If your patient is willing to submit to operation, knowing the dangers, the surgeon should be willing to take the risk even if as low a percentage as one in a hundred is cured.

DR. C. H. NORRED, Minneapolis—I simply want to relate a case, not operated upon, that made a brilliant recovery. In 1869 a child between 2 and 3 years of age, in running, drew a peanut kernel into the bifurcation. At that time we were not operating upon the lungs, and I treated the case expectantly. The patient, however, developed a typhoid pneumonia, and I called to my assistance Drs. Burrough and Henry, of Springfield, Ill. They assured me that my patient was beyond help. I noticed that in the paroxysms of coughing the child would get the peanut kernel up just so far and a spasmodic contraction would take place, everything would stop and cease and a desperate strangulation would result. I suggested that we relax the patient most completely, then give the child an emetic. The child was given morphia; we provoked vomiting and secured in a bowl the peanut. We finally succeeded in handling the complications and the child recovered.

DR. W. W. KEEN, Philadelphia—Some time since I had occasion to attempt to reach a cavity in the lung that was filled with pus, and I made the incision at the point that was indicated by my medical colleague after percussion of the lung, between the second and third ribs on the right side. I made my incision parallel to the ribs for about two inches; then carefully dissecting the muscles, separating them as I went down, with a cut and separation, I reached the pleura, which was very easily recognized. The muscles were very easily separated from the pleura. I could see the excursion of the lung up and down as it fell away to a certain extent from the surface. As there were no adhesions it was clear that it would be unsafe to puncture the lungs if there was any pus there. Accordingly, when the lung was at the moment of rest between inspiration and expiration, I took a Hagedorn needle and passed it quickly through the lung itself. Two stitches secured the lung in position. I then packed the wound lightly with iodoform gauze and closed it with two stitches. After three days I reopened the wound, removed the packing and had the gratification of finding a perfectly adherent lung.

This led me still further some time since, in a case that I reported at the American Surgical Association. It was the case of a woman who had sarcoma of the chest wall, reaching from the outer border of the breast nearly all the way back to the vertebral column, and I was obliged to remove a portion of the chest wall, into which my hand would precisely fit. When this was removed the lung collapsed. I had the Fell-O'Dwyer apparatus ready for use, but fortunately in this case there was very little embarrassment of the respiration as a result of the collapse of the lung. I then introduced my left hand and seized the lung bodily—it was not invaded by the tumor—drew it forward and with a long thread of catgut and a Hagedorn needle, sutured the lung completely around the opening by a continuous suture, with a view of preventing, as far as possible, pneumothorax. Then, I replaced the flap of skin and sutured it and sealed with iodoform and collodion. The patient made a fair recovery from the operation, but had a continued fever, which led me to have a blood examination made, and I found the staphylococcus infection in the blood. This was met by the use of the antistreptococcus serum, and the patient made a complete and very satisfactory recovery. The point I wish to emphasize is the means of obtaining adhesions where none exist so that we can carry out later in a punctured lung that which may be necessary, and secondly the safety even of a very large suture of the lung tissue to the chest wall, either as in the first case locally, or, as in the second, where there is a very large area in its surface.

DR. W. J. MEANS, Columbus—In the last two years I have had several cases of chest and lung troubles on which I operated. One of these cases demonstrated the possibility of recovery after a fearful gunshot wound penetrating the chest and producing extensive laceration of the lung. A boy, 16 years old, was out hunting with an old-fashioned muzzle-loading shotgun. It was accidentally discharged and the charge entered the chest below the axilla. The sixth and seventh ribs were broken, and the middle and lower lobes of the lung lacerated. The pleural cavity, when I saw him, was largely distended with blood clots. The opening was enlarged so that I could introduce my hand. When the débris was removed there was a very decided collapse. For a few minutes it looked

as though death was imminent. To control the hemorrhage I packed the cavity with iodoform gauze; several yards were used. The heart soon became stronger and the respirations more rhythmical and full. The packing was removed forty-eight hours later, when the same alarming symptoms appeared and disappeared on repacking the cavity. This phenomenon was present at every removal of the packing for some two weeks. This seems to have been a practical demonstration of the physiologic principle of the effects of destroying the equilibrium in the viscera of the chest. I recall another case illustrating the difficulty in the way of reaching an abscess cavity in the lung. The location of the abscess had been defined by an expert diagnostician. An opening was made in the chest wall corresponding with the supposed abscess. The pleural surfaces were found adherent, but no cavity. The patient had been expectorating an offensive pus for some time. The lung was explored in different directions, but no cavity could be located. The lung tissue at the point of opening was diseased and undergoing degeneration. A large opening was made through the chest wall and drainage established into the diseased lung substance. At intervals of forty-eight hours the diseased area was injected with iodoform emulsion. The patient recovered from the operation, but died four or five months later. I mention this to illustrate the difficulty in locating a cavity, and the fact that local treatment of tubercular areas of the lung will not always control the disease.

Dr. De Forest Willard, in reply—When the foreign body is not removed septic pneumonia frequently results with the formation of an abscess. Such an abscess should be opened and drained. Adhesions can be speedily produced between the two walls of the pleura so as to close off the pleural cavity before opening an abscess. With a strongly curved perineal needle with handle, a parallelogram of sutures can be carried around the area and the abscess opened at once, or twenty-four hours later. The same method may be employed in opening abscesses in the liver through the chest wall. A rib should first be resected subperiosteally, then a small amount of air should be allowed to enter the pleural cavity so as to permit the lung to recede slightly. The outer surface of the pleura and the diaphragmatic layer should then be sutured as above described, after which the liver can be reached across the pleural space, and pus evacuated without infecting the pleural cavity.

In regard to resection of the ribs, which has been alluded to this afternoon, I never use the bone forceps, since they are clumsy and are very likely to wound the pleura. With an extra-heavy flat-bladed rongeur forceps a rib can be cut through in a moment, turned back, and lifted out for any distance desired for resection, the second section of the bone being made with the same rongeurs.

THE TREATMENT OF STRABISMUS OTHER THAN OPERATIVE.*

EDWARD JACKSON, A.M., M.D.

Ophthalmologist to the Arapahoe County Hospital; Consultant in Ophthalmology to St. Anthony's Hospital, Denver; Emeritus Professor of Diseases of the Eye, Philadelphia Polyclinic.

DENVER, COLO.

Important as is the operative treatment of squint, it is less widely applicable than the non-operative treatment. A large proportion of cases may be cured without operation. The number so cured will increase, as it becomes customary to resort to the proper measures, as soon as the deviation is noticed. But in all cases some non-operative treatment is essential to effect a perfect cure. It may not be required only in that small class of operative cases in which binocular vision and normal ocular movements are not hoped for; but in which by operation we may lessen a deformity that we can not wholly remove.

The non-operative treatment for strabismus includes the entire treatment of many cases, and the earliest treatment for all. The indications to be met by it are: 1, to bring about normal innervation of the muscles concerned in ocular movements, by the removal and exclusion of abnormal requirements, and abnormal overflow impulses; 2, to place and keep the eyes, so far as possible, upon the best plane of visual acuteness and an equality of required effort; 3, to eradicate abnormal methods of using the eyes, especially dependence upon one eye to the practical exclusion of the other; 4, to develop normal binocular vision—the method of combining the visual sensations produced by the two eyes; and the habit of employing them both in all ordinary seeing.

For the majority of cases, the time for this treatment begins as soon as the squint is first noticed. The problem of controlling the activities of a young child, and directing them along certain lines, is indeed a difficult one. But since the nerve-muscle apparatus that we are endeavoring to perfect is thoroughly plastic only during the earliest years, these difficulties must be grappled with. In the main, what I have to say in this paper deals with this most important phase of the subject. The modifications advisable for more developed patients can be very briefly indicated.

The aim of the non-operative treatment, as it is the highest aim of the operative treatment of strabismus, is the establishment of binocular vision. Of this there are many grades, beginning with consciousness of impressions made on the two eyes, and extending up to the most perfect appreciation of relative distance and relief. Probably something like binocular vision, something more than mere extension of the field by the squinting eye, exists in many cases of strabismus and may constitute an obstacle to the cure of squint. It is certain that binocular vision is possible even when the vision in one eye is extremely imperfect.

In a patient suffering from high myopia, whose vision with correcting lenses was 4/80 in the right eye and 4/9 partly in the left, were recently encountered all the difficulties of adaptation that one would expect when prescribing lenses of unequal strength for eyes with perfect vision. In a young woman whose vision in the right eye was reduced to counting fingers at 8 feet, while in the left eye it was 4/4 mostly, repeated trials of lenses correcting a part of her anisometropia ended in failure. The disturbances of binocular vision were so marked that she would not wear them. In cases of this kind, the usual tests for binocular vision may bring no response. But we can not doubt that binocular vision of a kind is thoroughly established.

The things to be accomplished in the treatment of strabismus may be classified thus: 1. The removal so far as possible of all obstacles to binocular vision. Under this head falls the operative, with a very important part of the non-operative treatment. 2. The establishment of binocular vision. 3. The perfecting of binocular vision. The latter two are to be effected wholly by the non-operative treatment.

When the patient is able to perceive simultaneously impressions made on the two eyes, binocular vision of some kind exists. The efficiency of the function is at first to be estimated by the ability to keep fused the images, under varied conditions of accommodation and convergence. Mr. C. Worth makes the ability to do

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

this the second stage in the development of binocular vision. But I think that some power of maintaining fusion with altered accommodation or convergence begins as soon as there is ability to accomplish real fusion, although at first this power of maintaining fusion is very slight.

The development of the higher grades of binocular visual ability requires almost infinite practice. It may be compared in this respect with the higher grades of ability to play the piano or violin, or the mastery of the most delicate modulations of the voice. It must be acquired through the habitual use of the eyes in daily life, with such aid from glasses or suggested methods as we can give. It will not be reached merely through prescribed special exercises. With such exercises and the apparatus they require, we can only aim to bring about the rudest kind of binocular vision, and start it on the proper lines of development; although, in spite of the limitations of their usefulness, we must consider the most valuable of these appliances and prescribed methods.

Lenses.—In practical importance correcting lenses far outweigh all other measures for the non-operative treatment of squint. They remove the most common and serious obstacles to binocular vision that are removable. Their determination and use is the first step in the treatment of all cases. We can not in this discussion consider all the special indications to be met by lenses. But in every case the lenses should accurately correct all of the ametropia. Such lenses should be worn until the complete cure of the squint, or complete failure to benefit, shows them to be no longer necessary. Failure to rightly employ lenses is the most common cause of failure to cure strabismus. A very large proportion of the failures of glasses to cure strabismus in the earlier years of life must be ascribed to the fact that the glasses do not correct the ametropia. In many of these cases the glasses have been fitted by opticians. But even when prescribed by ophthalmologists of reputation and experience, one can not be sure that they are "correcting" lenses.

Case 1.—I. A., aged 6, was seen in consultation with a careful surgeon of large experience in ophthalmic work, who had prescribed R. and L. +2.75 spherical. These had been worn about five months without any marked diminution of a high convergent squint, which had during that time changed from intermittent to constant. The correcting lenses required were really

R. +4.50 ⊂ +0.50Cy. ax. 90°.
L. +5.50 ⊂ +0.50Cy. ax. 90°.

The wearing of these promptly checked the squint.

Case 2.—E. L. H., a girl aged 7, had been noticed to squint when less than 2 years old, and had been promptly placed under the care of an ophthalmologist. She had worn glasses for three or four years. Those she was wearing had been prescribed by an ophthalmologist who had seen her within a few months. After repeated examinations, he had given the opinion that glasses would do nothing more for her. That an operation was necessary; and unless he were allowed to do an operation he would not continue in charge of the case.

The child was wearing
R. +3 S. ⊂ +0.50Cy. ax. 90°.
L. +3 S.
What she really required was
R. +6.50 S. ⊂ +0.50Cy. ax. 105°.
L. +6 S.

These were prescribed and the deviation which had been 30 to 60 centrads promptly disappeared. At the end of six weeks there remained not over 5 centrads of esophoria; and in six months the muscle balance with the lenses on was perfect.

The accurate correction of ametropia being the most important single measure in the treatment of squint, and this being most effective in the earliest stage, it follows that no one who can not measure refraction objectively, no one who can not apply skiascopy with sufficient accuracy to obtain by it the data for prescribing lenses, is competent to treat strabismus.

This sounds like an extreme statement. Judging by old standards of attainment and old methods of treatment it is unduly so. But the experience of the last five years has established a new standard of success in the treatment of convergent strabismus in children, to be attained only by a method of which the foundation is the accurate correction of the refraction, at an age when the patient can give no assistance as to its measurement. In view of this, any milder statement simply falls short of the truth. The total hyperopia must be corrected. Astigmatism or anisometropia of 1 D. or less may constitute a complete bar to the re-establishment, or the renewed development of binocular vision, when the tendency to give up binocular vision has once become manifest. A fault of this kind, that would very rarely cause squint, may have to be corrected before the squint can be cured.

It may seem tedious to dwell so much on this subject of correcting refraction, but to have devoted more than three-fourths of this paper to it would only have been to give it space proportioned to its relative importance; and the cases I have cited illustrate a failure to recognize that importance which I believe is still very common among us.

Use of the Previously Deviating Eye.—In the great majority of cases this is the first point to be effected. Even though both eyes may to some extent be used, if one is distinctly preferred to the other for accurate seeing, the difference in the facility with which they are employed becomes a positive obstacle to the re-establishment of binocular vision. In general, it must be assumed that the fixing eye had originally some advantage over the deviating eye. To this advantage is added the facility acquired by habitual use for weeks, months or years. The advantage that the fixing eye now has is thus very much increased. It will not be removed by a few brief attempts to use the eye that has heretofore deviated. Weeks, months or years of continuous dependence upon the previously deviating eye might fairly be expected to be necessary to overcome such a disadvantage. In view of this, it is surprising what may be gained in this direction by a very moderate use of the poorer eye. But it should be understood that in most cases this using of the worse eye can not possibly be overdone.

The occlusion pad or bandage, which completely excludes the better eye, is the only thing that will serve the purpose, if the vision of the squinting eye is very much reduced. For older persons, it can often be used but a small part of the time, but for very young children it may be kept on almost constantly, removing it only often enough and long enough to ensure the health of the covered eye.

The essentials of such a pad are, that it shall absolutely prevent vision with the covered eye; and that it shall act as little as possible like a poultice. The ordin-

ary roller bandage may be used, but generally some special form arranged with tapes will be found more available. If the child can be watched, a mass of absorbent cotton stuffed behind the correcting lens of the better eye will answer. But usually I find it better to hold the cotton in place by one or two strips of adhesive plaster, as with the simple dressing used after cataract extraction. To avoid the pulling on the skin when the plaster is removed, it may be applied to a piece that is left in contact with the skin continuously. The use of the occlusive pad should be continued until, if this be possible, the vision of the worse eye has so improved that it will be used for fixation when the other eye is kept under a cycloplegic.

The Use of Cycloplegics.—The so-called mydriatics are to be used in this connection for their power to produce cycloplegia, not merely to dilate the pupil. An enlarged pupil is not sufficient evidence that the drug is being used effectively. The slightest reaction of the pupil to light proves that the eye is not completely under the influence of the drug. It is necessary from time to time to test objectively the power of accommodation, or the absence of accommodation, to make sure that the cycloplegia is properly kept up.

In all cases, cycloplegia is required for the determination of the ametropia. It may then be continued in both eyes to prevent the abnormal innervation associated with accommodative effort. In cases of alternating squint, this is sometimes of particular value.

In monolateral squint, however, after the correction of the ametropia, the cycloplegia should more frequently be confined to the better eye. It thus serves as a means of compelling the use of the previously deviating eye. As above indicated, it can only be thus applied for those cases in which the paralysis of accommodation of the fixing eye, the other retaining its accommodation, causes the transfer of the squint. If cycloplegia of the better eye does not accomplish this, we must use the pad. But if it does cause the transfer of fixation, it is a measure superior to the pad, because it is constant in its influence, requires less attention, does not interfere with the health of the eye, and leaves binocular vision possible, under favorable circumstances, if there be a tendency to establish it.

When employed in this way, cycloplegia should be continued until fixation, even at a distance with correcting lenses, is most of the time done with the previously deviating eye, or until all gain in this direction has entirely ceased. The length of time that the mydriatics should be thus employed is somewhat proportioned to the age of the patient, or at least, to the duration of the strabismus. But it will usually extend to several months and may go on to years.

The use of a mydriatic formerly advocated, as a substitute for correcting lenses in children too young to wear glasses, is now a very limited one. Nearly all children old enough to have a decided strabismus, as distinguished from the irregular uncoördinated eye movements of infancy, are old enough to wear glasses. They will wear them without objection if the ametropia be high enough to be of much importance, and the eyes are kept under a mydriatic for a few days after the glasses are put on.

But the mydriatic can not fully replace correcting lenses. It may remove the tendencies associated with excessive effort of accommodation, but it does not bring up the vision of the poorer eye, or place it more nearly on a plane with its fellow, as regards effort necessary for use. It removes an important cause of squint, but it does not, like the correcting lenses, bring about the conditions most favorable to the development of binocular vision.

Exercises for the Development of Binocular Vision.—The first thing aimed at, is to induce the patient to see with both eyes at once. This is first to be effected by using most striking objects. The light used for the subjective measurement of squint or heterophoria is a good object to begin with. The bringing about of diplopia, measuring the separation of the images, varying their relative position with prisms, and their relative strength by the use of dark glasses before the better eye, are excellent exercises of this kind. For young children such exercises must be of the simplest character, and on this account the fusion tubes of Priestly Smith are of especial value. They are two entirely separate tubes to be held by the child, one in each hand. This giving of something for the hands to do, and the freedom of movement, and the variety of movements which may be made, aid in keeping up the child's interest in the exercises. Sometimes it may be necessary to enfeeble the image of the better eye by use of a dark glass, or of a piece of paper of the proper thickness and translucently pasted over the tube used for this eye. But generally if the two streaks can be seen no such modification is necessary.

The Reflecting Stereoscope.—Next to the fusion tubes may be placed Worth's modification of the reflecting stereoscope. It is more adaptable and more rudimentary than the ordinary stereoscope. It can be used for lateral deviations in the same way as the fusion tubes; and in the main it offers the exercises of a stereoscope. It furnishes employment for the child's hands, and the figures used with it may be indefinitely multiplied.

The Ordinary Stereoscope.—This is of service for certain very valuable exercises and its range of usefulness may be extended by employing specially prepared pictures. The ordinary stereoscopic lenses are so decentered that they act as prisms with the base out. The distance between the optical centers of the two lenses is about 85 mm. With an ordinary pupillary distance of 61 mm., this gives a decentering of 12 mm. for each lens; or with the 5 D. lenses usually employed gives a prismatic effect of 6 centrads for each eye. For children with a small distance between pupils, the decentering is still greater. For 55 mm. it would be 7.5 centrads prismatic effect. The pictures ordinarily used in the stereoscope are so broad, 85 mm., that the prismatic effect is required to render parallel the rays which enter the two eyes from corresponding points of the two pictures. If we make the pictures narrower, and bring them correspondingly closer together, the same prismatic effect will allow them to be seen with convergence. Thus, for a child with a distance between the pupils of 51 mm., pictures 51 mm. wide, placed in close contact. will have their corresponding points fused with a convergence of 34 centrads—almost 20°. These narrower pictures are very readily made by cutting down larger pictures, or in drawing the rude diagrams that often prove serviceable in the orthoptic training of young children.

The stereoscopes arranged for the adjustment of the width of the glasses, or the positions of the pictures, or both, are capable of the same service, and of other uses. But I shall here dwell only on the more common form of the instrument; because its simplicity gives it a much wider range of application. That instrument

is of the most value which can be trusted to the child under the supervision of the parent or caretaker, rather than one to be used for a brief time in the office of the surgeon.

As has been indicated above, these exercises must be practiced a considerable portion of the time to be of great service. The object of the first exercises with the stereoscope is to cultivate the ability to see with both eyes at once. For this purpose a series of pictures is required, the two halves of which differ, but are so related that they may be appropriately superimposed. The picture of the bird presented to one eye, and its cage to the other, is typical of this sort. The stimulus to co-ordinate action is given, when the child is induced to try to get the bird into the cage, or into the center of the cage. Exercises of this character prepare the way for more advanced efforts. They also remain of great use throughout the treatment. Even when normal binocular vision has become habitual, it is worth while to recur to them.

If the child has previously had some practice with fusion tubes, the second class of pictures may soon be brought into use. In these, some portion is common to both pictures. This portion must be fused to avoid diplopia, while the completeness of the picture proves that single vision is not obtained by excluding one eye. Pictures of this sort are less interesting to the child, because their component parts have a single fixed relation; and do not offer the same opportunity of conscious adjustment. On this account one should have a large series of them and should supply them a few at a time. They may be made out of ordinary stereoscope pictures by cutting off different corners from each, or by placing a dot on one, and a cross on the other, and making sure that the whole picture, or both dot and cross are seen.

When binocular fusion is well advanced, the distance between the pictures and the lenses may be varied. If the pictures be wider than the pupillary distance of the patient, variation of the distance from the eye will cause slight variations in the actual amount of convergence. If the width between corresponding points of the pictures equals the pupillary distance, pushing them nearer to or farther from the lenses will make no difference in the convergence required. But it will alter the necessary state of accommodation; and a change of relative accommodation is an exercise of very much the same value as change in relative convergence.

The Reading Bar.—One other practical device remains to be noticed—the reading bar. It provides a highly specialized exercise, depending for its value on the fact that our printing arranges words in long lines, each of which must be followed throughout its whole extent in rapid succession. The bar excludes the habitually seeing eye from seeing some portion of each line, compelling the use of the deviating eye for that part of the time. It has the advantage that it can be employed while pursuing a customary occupation. This is a great advantage within its somewhat narrow sphere of usefulness. I have found it of most value in the preparation of older patients for operation: and in establishing a new co-ordination of eye movements after operation.

Increase in Population in France.—The latest census shows that France has gained 412,364 inhabitants during the last four years. The *Sem. Méd.* adds that this is three times the gain of the preceding four years.

THE STRABISMUS OPERATION.*

C. F. CLARK, M.D.
COLUMBUS, OHIO.

Though a somewhat hackneyed subject, the last word has not yet been spoken upon the strabismus operation, nor will it be for many years to come. While without doubt it is true that excellent results may be obtained in the correction of strabismus by a variety of operative procedures, it is also true, as I think every operator present will acknowledge, that there is a diversity in the results of this operation which plainly indicates that perfection has not yet been obtained. I offer no apology for occupying your time with the consideration of a department of ophthalmic surgery on which such diverse opinions are expressed as we may find in the text-books and articles which appear from time to time on the various phases of this subject.

An analysis of the opinions expressed by a limited number of operators of national and even international reputation will show a divergence of views not only as to details, but on such important points as the following: 1, as to the degree of deviation and the character of the cases which they consider proper subjects for operation; 2, as to the age at which an operation should be performed; 3, as to the choice between tenotomy and advancement; 4, as to the amount of deviation that may be safely corrected by tenotomy; 5, as to whether the operation should be confined to the eye which most constantly deviates or its effect distributed between the two eyes so as to preserve the ocular balance; 6, as to full correction of the error in the first operation or delaying a portion of the operative procedure until the effect of the first division may be properly estimated; 7, as to the practicability of partial, or graduated tenotomy or advancement; 8, as to the value of orthoptic exercises before and after operation; 9, as to the value of tests made with prisms and otherwise during the progress of an operation; 10, as to the importance of the subconjunctival method of Snellen and of suturing the conjunctival wound; 11, as to the necessity of bandaging one or both eyes after an operation for tenotomy or advancement; 12, as to the relative importance of operations upon the superior and inferior recti muscles in cases of hyperphoria and hypertrophia associated with lateral deviations, and 13, as to the most approved form of operation for tenotomy and advancement.

I fully realize that different methods will always have their advocates and it is no part of my intention to undertake to harmonize the views of the members of this Section, but in view of the divergence of theories and methods of procedure which now prevail, is it not proper that each of us should study the plan pursued by his associates and assure himself that he has not been committing that common error of successful surgeons of being too well satisfied with his own methods and results? I am persuaded that when the last word has been spoken on this subject we will have greater consistency in methods and far greater uniformity in results than now prevail.

Dr. Herman Knapp in his excellent chapter on operations,[1] makes the following statements: "1. After a tenotomy of the internal rectus the primary effect is apt to diminish for several days, but then, as a rule, it increases gradually for weeks, months and years. In

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

1. Norris and Oliver's "System of Diseases of the Eye," vol. iii.

many cases we rejoice at having obtained a perfect cosmetic result, but when we see our patient again in later years his eyes diverge more or less. 2. The immediate effect of a tenotomy of the external rectus increases the next three or four days, then it diminishes very gradually, so that the ultimate result is frequently not more than two or three millimeters, and at times it disappears altogether."

An over-correction after division of the internal, and an under-correction after division of the external rectus is then of not infrequent occurrence after a tenotomy even when performed by so careful an operator as Dr. Knapp, and I think every operator of wide experience will agree with me that, in spite of the most painstaking observance of every rule which prudence may dictate, in the correction of high degrees of convergence, we are often disappointed in our final results.

In contrast with this note the following statement made by Landolt,[2] who for a number of years past has been advocating the substitution of advancement for tenotomy as a routine measure: "In twenty years' practice we have never had an over-correction after advancement, which is frequent after tenotomy. We have never produced a strabismus, which can hardly be avoided after tenotomy, at least in the secondary position. The advancement has also the cosmetic advantage of not causing annoying protrusion of the eyeball, sinking of the caruncle, or exposure of the sclera."

If one of these plans of procedure is correct the other is certainly questionable, and yet there are many advocates of each. By far the majority seem, at least in their practice, to still prefer tenotomy when it can be made to serve their present purpose. It is more in keeping with our traditions and is less tedious; but it is a significant fact that, while even approximately perfect equilibrium of the ocular muscles after well-marked strabismus is, as we all realize, most difficult of attainment, such a result is claimed in many instances by those who advocate Landolt's method, and are willing to take infinite pains to obtain it.

A few years ago there was, as will be remembered, a strong reaction against those extremists who claimed to be able to work miracles in all nervous diseases by slight-of-hand performances upon the ocular muscles. This reaction was timely and proper, but we should not be led so far in the direction of conservatism as to prevent our accepting and adopting every improvement in method and technique which has a rational basis.

A careful review of the subject and what personal experience I have had in this direction, leads me to make the prediction that within a few years many of those who have heretofore depended mainly upon tenotomy for the correction of strabismus will find themselves adopting the more tedious but far more conservative operation of advancement, or resection almost as a routine practice.

While, for the purposes of this paper, it is not practicable to consider fully the anatomy of the ocular muscles, there are a few practical points which it will be well to review before passing on to the subject of operations. The oculo-orbital fascia, in the descriptions of which great variations are found, should be dealt with as a mass of more or less condensed connective-tissue fibers, differentiated into a dense membrane in certain portions, while in others it is made up of somewhat loose connective tissue joining the conjunctiva to the eyeball and to the sheaths of the tendons of the recti muscles and also uniting the sheaths of these muscles somewhat loosely to the sclera. The lateral or restraining fibers connect the sheaths of the muscles with the more condensed portions known as Tenon's capsule. The effect of this anatomical arrangement is that a division of the tendon at its insertion, provided the lateral fibers remain intact, results in a limited retraction of the tendon and its secondary insertion at a point only a short distance posterior to its former point of union with the sclera. The passing of a hook beneath the tendon and breaking up of the loose fibers which unite its sheath with the sclera, adds very little to this retraction. The division of the fibers which unite the sheath of the muscle with the conjunctiva, adds more to the power of retraction, but if we wish to obtain free retraction of the muscle we must divide the lateral fibers connecting it with the more dense portions of Tenon's capsule which lies between the muscles, or what in fact amounts to the same thing, separate this capsule from the sclera above and below the point of insertion of the tendon. The foundation of all theories which deal with the subject of tenotomy and advancement lies in the relations of the tendons and muscles to this oculo-orbital fascia, or to be more exact, that portion of it which is termed Tenon's capsule. The tendons of the recti muscles are inserted at points varying somewhat in distance from the margin of the cornea: The internal rectus at a distance of 5.5 mm., the inferior 6.5 mm., the external 6.9 mm., and the superior 7.7 mm. The widths of the tendons also differ in the following order: internal 10.3 mm., inferior 9.8 mm., external 9.2 mm., superior 10.6 mm.—Fuchs. In length the tendon of the internal is 8.8 mm., the inferior 5.5 mm., the external 3.7 mm., and the superior 5.8 mm.—Merkel.

It is well in operating to remember also the peculiar insertion of the superior rectus muscle. It is quite wide, and at the nasal side is inserted much farther forward than at the temporal. It is so set that the bulk of its insertion is on the outer half of the eyeball. The inferior rectus on the other hand is so inserted that its temporal border is slightly in advance of the nasal. The measurement (3.7 mm.) given above by Merkel as the average length of the tendon of the external rectus muscle, does not conform to the impression I have obtained in the advancements and tenotomies which I have made.

In a number of resections of this tendon I have removed more than 3.7 mm., and obtained excellent results. It is possible that in doing so I may have included some of the muscular fibers.

For our purpose the various operations resorted to for the correction of strabismus may be classified under the following heads:

Tenotomy.—1. Partial division of the tendon (graduated tenotomy). 2. Complete division of the tendon. 3. Complete division of the tendon, with division of the lateral fibers of the capsule.

Advancement.—1. Partial advancement of the tendon (graduated advancement). 2. Complete advancement of the tendon. 3. Complete advancement of the tendon with advancement of the capsule. 4. Resection of the tendon. 5. Resection of the tendon and capsule.

In all of our operations for the correction of strabismus, the following general rule should be observed and exceptions to it are seldom justifiable: Whether we operate by tenotomy or adopt the more conservative method of advancement, the effect of the operation must be so distributed between the various muscles as to preserve the control of the eye in all ordinary movements.

2. Archives of Ophthalmology, vol. xxvi. p. 8.

A simple tenotomy will, according to Fuchs, correct about 3 or 4 mm. of convergence. In divergent strabismus, he has found that a simple tenotomy will not correct more than 2 mm. as an average. In view of the effects which we have all obtained in some of our earlier operations, this rule seems extremely conservative, but if we confine our division to the tendon at its point of insertion and avoid division of its lateral attachments, I do not believe it is safe to expect a much greater result than he has indicated, and in my own operations where I have depended upon tenotomy, I have seldom gone far beyond this limit without having reason to regret it.

Many rules have been laid down to enable the operator to avoid the excessive effects which often follow as a late result of tenotomy, but in difficult cases it not infrequently happens that, in order to obtain even a moderate degree of correction, these rules are violated. When more than 3 mm. of convergence, or 2 mm. of divergence is present, if tenotomy is relied upon, the effect should be divided between the two eyes rather than by operating upon one alone to obtain a correction at the expense of a free division of the lateral attachments.

Knapp lays down the following rules to govern the operator in tenotomy: "A. As a rule no squint operation should weaken the muscle beyond its physiological limit of power. B. After a tenotomy of the internal rectus, the result of the immediate examination should be as follows: 1. In adduction the medial margin of the cornea should readily reach the caruncle. 2. The near point of binocular fixation should not be less than 5 centimeters—two and one-half inches. 3. The eyeball should not protrude. 4. There should be some convergence left."

If these rules are strictly adhered to and the lateral fibers are left undisturbed, we may undoubtedly avoid an—immediate—over-correction, but the weak point in such a system of rules is that, if strictly adhered to, only a slight correction of 3 or 4 mm. is obtained and, even if the operation is divided between the two eyes, a careful examination of the field of fixation will almost certainly reveal some limitation of motion.

How often it has happened in the experience of each of us that after such a tenotomy the immediate result has been not only insufficient but almost nil and to save ourselves and the patient from the chagrin of a sense of failure, we have divided first a few and then a few more of the lateral fibers and then wondered whether we would not at some future time discover that we had slightly over-corrected the error.

Now it is a fact that even the setting back of the tendon alone, if it is sufficient to give us 3 or 4 mm. of correction must, to a limited degree, restrict motion and violate the spirit of the first of these general rules.

The very essence of such an operation consists in the fact that the control which the muscle exercises over the eye is made less effective, whereas it should be our object not to lessen but to increase this control. The movement of an eye, in a given direction, depends not alone upon the contraction of the single muscle which turns it in that direction but also, and only to a less degree, upon the co-ordinated movement of its antagonist, while both of these must again act in harmony with the corresponding muscles of the other eye. In any squint not dependent upon paralysis or traumatism, surgical or otherwise, of one of the muscles the squinting eye, while having an improper direction, still moves in harmony with its fellow and its excursions are usually of the same amplitude. If we wish to preserve the harmonious relation of the four muscles which take part in this somewhat complicated act of co-ordination is it reasonable to begin by an avowed attempt to cripple one of them?

It is a mistake, as Landolt has pointed out, to suppose that the antagonist gains in strength what the tenotomized muscle loses and, even if it did, it is not proven that the muscle we divide has more strength or more power to move the eye than it should have. It is a question not of power but of direction with which we are dealing and the choice between tenotomy and advancement reduces itself to this: Is it better that the group of four muscles acting to produce harmonious movements of the two eyes, should have the aggregate of control which they exercise over the eyes increased by giving one of its members a more advantageous attachment, or diminished by setting another back and thereby lessening its control?

In the latter case we gain the proper direction, but in so doing we make a distinct sacrifice of a portion of the control which the group exercised over the eye, while in the former we also gain the proper direction but increase the aggregate of control by giving to one of the members an advantage in moving the eye which may be exercised or not as circumstances may demand.

I do not wish to be understood as advocating so radical a change in the accepted method of dealing with squint as the entire substitution of advancement for tenotomy, though that would seem to be the logical outcome of the above reasoning.

Advancement is so tedious and tenotomy so simple an operation that the latter will probably always be preferred in slight deviations, but whenever a deviation exceeds 5 mm. it is proper to raise the question whether an advancement should not be substituted for tenotomy; and whenever in any case of tenotomy it is found that the proper effect can not be produced without considerable division of the lateral attachments of the tendons an advancement should be substituted or should supplement the tenotomy.

As to the best method of performing a tenotomy or advancement, it is my opinion that equally good results may be obtained in a variety of ways, provided certain general principles are observed, and it is with general principles that we are here dealing rather than with the details of special methods of operating. these principles the most important relates to the division of the effect between the various muscles and the preservation of as complete control of the eye by each muscle as may be practicable. If the deviation is slight and a tenotomy is decided upon I greatly prefer the method of Snellen as modified by Stevens—a sub-conjunctival operation—buttonholing the conjunctiva and tendon and cutting both ways. But in those relatively frequent cases in which, after the first incision, there is well-marked hemorrhage beneath the conjunctiva, I at once convert the small incision into a large open wound in order to avoid a troublesome sub-conjunctival thrombus.

Careful measurements, linear, angular and by prisms, before, during and after the operation, I consider of the utmost importance, but in cases in which there is marked amblyopia we must judge mainly by inspection and for this purpose there is a great advantage in operating in a dental or other reclining chair and in having the patient in the upright position while testing so that the operator may stand off at a distance of eight or ten feet

and observe the movements of the eyes. An examination made at the near point is often very misleading. If the operation is divided between the various muscles of the affected group and, in case the deviation is marked, is corrected mainly by a well-performed advancement or resection, measurements are of great value, but in the old method of operating in which the tendon was divided at one cut and what deviation remained was corrected by free division of the lateral attachments, the eye became so unstable that measurements made at the time of operation afforded very little information as to what the final position of the eyes would be.

It is not infrequently the case after a carefully performed operation for convergent strabismus as a result of which the eyes occupy approximately the proper position, to have, owing to the presence of what is sometimes termed a false macula, a well-marked heteronymous diplopia with the images widely separated.

This is probably due to what Dr. Berens has well termed "neuro-muscular memory," and should not disconcert us as it seldom causes serious disturbance, though it may make it more difficult to judge of the accuracy of the result obtained. We are, in fact, forced in such cases to depend entirely upon objective tests. It must, of course, be borne in mind that the more extensive the traumatism inflicted during the operation the more unreliable are the results of measurements made immediately after operating, and this is an additional argument in favor of advancement in its various forms, as by this means we seldom have an over-correction and by allowing a portion of the deviation to remain, we may at a subsequent operation gauge the result accurately in a supplemental tenotomy, correcting the slight remaining defect.

In tenotomy we should, so far as may be practicable, let the capsular attachments alone if we wish to avoid crippling the combined movements of the eyes, but in advancement or resection it is desirable, in our attempts to increase the control exercised by a given muscle, to bring forward or shorten the capsule with the tendon. In so doing we gain another advantage which is of great importance, in obtaining a firm hold for our sutures. In fact, in the resections which I have performed of late, I have made free use of sutures, practically quilting the tendon and capsule together, and have thus avoided a very annoying feature of some of my former advancements in which the effect would be in part lost within a few days owing to the insufficient and uncertain hold obtained by sutures introduced in the usual manner in the tendon alone.

While it has been greatly improved within a few years, there is room for still greater improvement in the operation for advancement. Before the days of asepsis advancement was indeed a formidable operation, often being followed by decided reaction, and even as now practiced when we compare it with tenotomy it is not strange that a beginner in ophthalmic surgery should, when in doubt, prefer the latter. But the question of a little more or less annoying detail in the operation should not be allowed to weigh against any advantage we may gain for our patients, and advancement should be unhesitatingly performed when it is apparent that it will produce a better final result.

The old operation, by which the tendon is split in its center and one portion drawn forward above and the other below the cornea, while certainly effective, has seemed to the writer unnecessarily complicated. Any method which, with a freely exposed field of operation, succeeds in securing and evenly mooring the tendon and capsule of Tenon to the sclera at a point well in advance of its former point of attachment will accomplish the desired end and, in cases of less marked deviation, a method which resects a sufficient amount of the tendon and capsule and firmly sutures the distal to the proximal portion will also yield an excellent result.

Because of the thorough manner in which the field of operation is exposed, probably no method is a greater favorite with those who have tried it than that devised by Dr. Savage of Nashville, by which an L-shaped primary incision is made, one side of which is parallel with the line of insertion, and the other parallel with one border of the tendon and the flap turned well back and held out of the way by a suture while the tendon is advanced or resected.

The method of capsular advancement advocated by Dr. Fox of Philadelphia for cases in which there is extreme deviation certainly has the advantage of simplicity and the results he reported to this Section last year were excellent, but I have been thus far deterred from adopting it owing to the amount of traumatism inflicted and a feeling that I would prefer to see the tissue with which I am dealing in an operation of such delicacy.

With the exception of those cases in which the degree of deviation is excessive, resection affords excellent results and for several years I have been endeavoring to discover some method by which I could simplify the ordinary procedure and substitute it, so far as is practicable, for tenotomy. I found that by introducing a tenotomy hook in the ordinary manner and then seizing the fold of tendon beneath the hook with Prince's advancement forceps, I could gauge the amount of tendon removed by the point at which the forceps' blades were applied and suture it thoroughly and evenly at my leisure.

This led me to devise the small double hook which is figured in the report of this Section for last year and which in a number of instances has since served an excellent purpose.

After making a vertical conjunctival incision as long as, and one or two millimeters behind the insertion of the tendon, I make in Tenon's capsule two short cuts with the scissors parallel with and a short distance above and below the tendon and extending from its point of insertion backward to a distance equal to the amount of shortening desired. The central blade of the hook is now inserted below and made to include the tendon and that portion of Tenon's capsule which covers it and by turning the milled head this central hook with the tendon and overlying capsule is drawn up between the other two blades to such a distance as may be desired. Interwoven sutures are then inserted, firmly stitching the two surfaces of the folded tendon together, after which the hook is removed, the apex of the fold cut away with the scissors and the conjunctival wound closed with fine silk sutures.

A comparison of the writings of various acknowledged authorities on strabismus reveals in the after-treatment the same diversity of opinion as is observed in other departments of this subject. While Dr. Duane of New York prefers after tenotomy to keep the eyes open and practice orthoptic exercises before the wound is firmly united in order to obtain binocular fixation, Dr. Landolt, on the other hand, keeps both eyes bandaged during the healing process, often insisting upon the patient remaining in bed for six days. Between these extremes we may find every variety of directions given to patients as to

their conduct after operation, which only proves that, as in other departments of surgery, fair results may be obtained in a variety of ways. And, while I have obtained good results by the course I have pursued, which may be said to be midway between these extremes, I am free to admit that it would give me the greatest pleasure to be able to observe minutely the progress from day to day of the patients treated by both the methods described, as certainly Dr. Landolt's reports indicate a higher standard of final results than is claimed by many operators, and under such circumstances it is becoming that we should at least hold our minds open to conviction.

In conclusion, I would state as my conviction that, in the correction of strabismus, advancement, or resection combined with a very limited tenotomy, should, as a rule, be substituted for simple tenotomy.

ARTIFICIALLY PREPARED FOODS, THEIR NUTRITIVE VALUE AND DIETETIC APPLICATION.

L. BREISACHER, M.D.

Consulting Gastro-enterologist, Harper Hospital; Formerly Professor of Comparative Physiology, University of Pennsylvania: Member of American Physiological Society.

DETROIT, MICH.

The history of the scientific production of artificially prepared foods, like that of the subjects of digestion, nutrition and metabolism, is nothing more than a summary of the achievements of the experimental sciences relating to general biology and the science of medicine.

Investigation of the various empiric dietetic systems, from the time of Aristotle up to the end of the eighteenth and the beginning of the nineteenth century, shows that, while various grain decoctions, ptisan, almond, egg and sugar-water and probably a few other dietetic preparations were used for invalids, no preparation existed which might lay claim to being an artificially prepared food in the sense that the term is used to-day. Far reaching and revolutionary were the discoveries which ushered in the birth of the exact knowledge of nutrition and dietetics![1] On the one hand we had the discovery of oxygen by Priestly and Scheele in 1774, and the subsequent development of the theory of oxidation by Lavoisier in 1780; on the other hand was the investigation of Spallanzani and Reaumer, in 1752, on the subject of digestion.

Let us here rapidly sketch the outlines of the growth of our subject and review the fundamental principles by which the nutritive value of foods may be judged and the nutritive demands of the human individual adjusted. In this manner we shall be able to appreciate the status of our subject and to determine the applicability of artificially prepared foods to the diet of man in health and disease.

Although from the time when Lavoisier defined the processes of oxidation, up to, and even beyond, the first quarter of the nineteenth century, considerable work had been done on the subject of nutrition, little was really accomplished until the theories of Liebig, the greatest chemist of that century, were shown to be incorrect. As late as 1842 very little was known of the nutritive and physiologic significance of albumin, fat and carbohydrates. It was during this period that Liebig believed that the destruction of albumin served the purpose of furnishing the organism with energy for the execution of mechanical work, while the oxidation of fats and carbohydrates was supposed to furnish heat to the body and protect the albumin from unnecessary oxidation. It was very soon shown, however, that this explanation was incorrect, for experimental evidence was brought forward which proved that the increased ingestion of albumin by an animal at rest was accompanied by a corresponding increase of nitrogen excretion. Important as was the demonstration of this fact, its exact significance was unfortunately misconstrued, and, in consequence, gave rise to much controversy and years of laborious experimentation. It was now taught that the minimum quantity of albumin necessary to the animal organism was expressed by the quantity of albumin disintegrated during inanition. Finally, during the years 1857-60, Bischoff, Voit and Pettenkofer published the results of their experimental work, and it was at this time really that the cornerstone of nutrition, as an exact science, was laid.

For the continued normal expressions of the functions of an organism, the ingestion of a certain and definite quantity of food is requisite. This general biologic law manifests itself, irrespective of theoretical speculation or scientific observation, in the expression of the instinctive impulse which guides every organic entity in its selection of the requisite quantity and quality of food. However, not until Helmholtz and Meyer formulated the theory of the conservation of energy, did we fully appreciate the philosophy of this law.

Every organic function is accompanied by the production of heat, which finds its origin in the oxidation of definite chemical combinations, the absorbed and assimilated products resulting from the digestion of substances termed foodstuffs. The amount of heat which an organism gives off is equivalent to the calorimetric value of the food which it requires in a given period of time. The food which the system requires is represented by the nutrient principles, albumin, carbohydrates and fat, each one of which may substitute or replace the other, but only, as we shall point out later, within the limit of their minimum nutritive or physiologic quantity. Irrespective of the relative proportions of each one of these food principles, the total heat requirement of the organism remains the same.

Every foodstuff possesses a certain caloric value, which is expressed by the term calorie, and each represents that quantity of heat necessary to raise one kilogram of water from 0 to 1 C. It is customary to express the total quantity of nutriment necessary to maintain the nutritive demands of an organism by the caloric value of the food introduced into the system. Instead of simply stating that the system requires so much each of fat, albumin and carbohydrates, we express it by the number of calories which the system requires in a given period of time under definite circumstances, presupposing always that these three foodstuffs be contained in certain proportions and in definite relationship to each other. Although this is a very convenient method and the one now generally followed, it is not strictly logical, because it neither embraces the valuation of the nutriment required to rebuild the wasted tissue of the body, nor, in the organism at rest, the amount of energy expended in the carrying on of circulation, heart beat, respiration, gastro-intestinal and glandular activity.

Expressing, therefore, only partly the metabolic significance of a given food, the caloric method is, nevertheless, the most convenient we have at our disposal at the present time. This method is founded upon the fact, to

1. Breisacher: The Principles of Metabolism and Nutrition.

which we have already alluded, that the amount of heat given off by an organism is practically equivalent to the calorimetric value of the food which has been introduced into it. When fat, albumin, carbohydrates or gelatin is subjected to calorimetric estimation it is found that each has a definite caloric value, thus one gram each of these foods equals the following: Albumin, 5.7 calories; gelatin, 5.5; fat, 9.3; starch, 4.1; cane sugar, 4.0, and glucose, 3.7 calories.

The method of calorimetric estimation of foodstuffs consists in introducing a given quantity of food material into a specially constructed bomb, which is filled with oxygen under a pressure of from fifteen to twenty-five atmospheres. After the bomb has been submerged in water, the substance under examination is ignited by means of electricity and an estimation made of the heat imparted to the water.

It has been shown that fats and carbohydrates when introduced into the system are oxidized into carbonic acid gas and water, and further, that when subjected to the action of a calorimeter they undergo a like change. With albumins, however, the matter is somewhat more complicated, for, while they are oxidized into nitrogen, carbonic acid gas, water and a small quantity of sulphuric acid in the calorimeter, in the animal organism they are split up into urea, uric acid, kreatin, kreatinin, hippuric acid, etc. To determine, therefore, the caloric value of albumin to the system it is necessary to subtract the caloric value of these organic oxidation products.

By this method of calculation we find that the physiologic nutritive value of albumin is 4.1, compared with its calorimetric value of 5.7. The physiologic heat or caloric value of fat and carbohydrates is identical with the calorimetric value. The physiologic or nutritive caloric value, therefore, of one gram of fat is 9.3, of one gram of carbohydrates, 4.1, and of one gram of albumin it is also 4.1. Fat, albumin and carbohydrates form the three chief nutrient principles which enter into the diet of a human individual. The necessary quantity of each one of these separate nutrient principles required by the system, and the relationship of one to the other, is dependent upon varying circumstances. The relationship of fat, carbohydrates and albumin in the diet of an infant is not identical with that in the diet of an adult, neither is the required relative quantity of these nutrient principles, estimated per kilogram body weight, the same in the mature as in the immature organism. Further, the demands of a weakly developed inactive organism are different from those of a laborer or an athlete. In accordance with the law of substitution, each nutrient principle may be substituted for the other, within its minimum physiologic limit, as recent experiments have conclusively shown.[2]

A thorough comprehension of these laws, which I shall define more particularly later on, is absolutely necessary in the rational feeding of both healthy individuals and invalids. The fundamental principles, upon which our entire knowledge of the subject of nutrition is founded, are the result of experiments made upon human individuals and animals. Among the most important are those experiments made upon fasting individuals. When food is absolutely withheld from a man weighing about 70 kilograms—154 pounds—for a period lasting from twenty-four hours to a number of weeks, it is found that the system loses from 50 to 80 grams of albumin and from 200 to 250 grams of fat, each day. In a single twenty-four-hour period the loss of water is from 800 to 1000 c. cm.; in longer periods, the subject of the experiment is usually given a sufficient amount of water to cover this loss.

The execution of a certain amount of mechanical labor during a period of fasting increases the fat consumption and water exhalation while the albumin waste remains the same as in the fasting individual at rest. It has further been shown that persons provided with an abundant supply of adipose tissue withstand the influence of fasting more effectually than lean individuals, for the reason that in the former the adipose tissue furnishes the major percentage of caloric demand of the organism, thus protecting the albumin supply from excessive waste.

The size or bulk of an individual also determines the total fat and albumin consumption of the system, and it has been demonstrated that, while the absolute quantity of albumin and fat may be greater in the larger individual than in the smaller one, the relative quantity of both of these foodstuffs, estimated per kilogram body weight, is greatly in excess in the smaller or less bulky individual, than in the larger one. This law is equally invariable, irrespective of whether the food consumption refers to a fasting or normally fed individual, or whether it be applied to an infant or an abnormally large or small adult. The nutritive demand per kilogram body weight, therefore, is in an inverse proportion to the size or bulk of the organism.

If an animal from which food has been withheld for a certain period of time, i. e., a number of days or weeks, be fed meat it will be found that the nitrogen excretion, as expressed by the nitrogen in the urine, is increased, and, with each additional increase of albumin (meat) to the diet, the excretion of nitrogen is increased proportionately. This increase of nitrogen excretion continues until sufficient amount of albumin (meat) has been added to the diet to effect a nitrogen balance, that is, a nutritive condition in which the nitrogen income is equal to the nitrogen outgo. It was taught by Voit that the quantity of albumin necessary to cover the albumin loss of the system was two and one-half times greater than the loss resulting during a period of fasting. This, however, is not strictly correct, as the writer and several other investigators showed in a series of nutrition experiments.[3]

In addition to the loss of albumin, the fasting individual suffers a distinct loss of fat from his organism, and it has been found that, by insuring the absorption of fat equivalent to the loss of adipose tissue during fasting, the fat consumption may be checked while the albumin destruction remains unchanged. It follows from this that the ingestion of fat by a fasting animal may prolong life, but not prevent ultimate death from starvation. The exclusive feeding of carbohydrates, like that of fat, does not prevent the occurrence of death by starvation, although they protect the system from albumin destruction more effectually than fat.

If a definite quantity of fat and albumin is given to an individual who has been subjected to a period of fasting, it will be noticed that the loss of organic or body albumin is arrested. This does not occur when simply fat or carbohydrates are given and which can not be practically achieved in the human being by an exclusively albumin diet. Fat, whether existing in the system as adipose tissue or introduced into the system as food, protects the organic albumin from undue waste.

2. Breisacher: (*a*), Eiweissbedarf beim Menschen; (*b*), Principles of Metabolism and Nutrition.

3. Breisacher: Eiweissbedarf beim Menschen.

When along with a requisite amount of albumin, more fat is introduced into the system than the total caloric demand requires, an increase in the supply of adipose tissue is achieved. When carbohydrates, in the form of sugar, starch or dextrin, are added to a diet composed simply of albumin, the destruction of the latter is lessened, and, as in the case of fat and albumin, if a sufficient quantity of carbohydrates be added to a requisite amount of albumin, the loss of organic albumin is arrested. Likewise, when carbohydrates are added to a combined fat and albumin diet, the total consumption of both of the latter is lessened. The effect, however, of like quantities each of fats and carbohydrates, in retarding albumin consumption, is not identical. Notwithstanding the fact that a gram of fat represents a caloric value, which is 5.2 greater than a gram of carbohydrates, it has less influence in checking albumin waste than the latter. As we have already pointed out, when an excess of fat is fed to an individual, a deposit of fat, in the form of adipose tissue, is effected; when an excess of carbohydrates is fed, an elaboration of fat, with a resulting increase of adipose tissue, takes place.

Gelatin is a nitrogenous substance resembling albumin in its atomic arrangement, in its conversion into peptone by the gastric and pancreatic secretions, and in its final oxidation into urea. When gelatin is added to an albumin diet, it has an influence in lessening organic albumin and fat dissipation similar to that possessed by both fat and carbohydrates. It is of interest to note that while gelatin has a more pronounced effect in lessening organic albumin destruction than both fats and carbohydrates, in reducing the organic fat dissipation it is less effectual than either fat or carbohydrates. Despite the chemical resemblance of gelatin to albumin it can not replace that substance, nor are we acquainted with any substance which can substitute the minimum physiologic nutritive quantity of albumin necessary to an animal organism.

These then are, in brief, the primary fundamental principles by which we must be guided in nourishing individuals, both in health and in disease. These principles emphasize the fact that of the three chief nutrients—albumin, fat and carbohydrates, to which a fourth, gelatin, may be added—albumin is the substance which requires the foremost consideration in the selection of a diet. This is true because it can not be replaced by any other known nutrient, irrespective of whether it belongs to the nitrogenous or non-nitrogenous group of chemicals or foodstuffs.

These principles further teach us that one or preferably both of the non-nitrogenous food principles, carbohydrates and fats, should be added to an albumin diet for the maintenance of the healthy functions of the organism. To these two non-nitrogenous nutrients we may add gelatin, which, as we have seen, has an influence similar to that of both fat and carbohydrates.

Let us here consider the exact quantity in which each one of these nutrient principles must be contained in the daily diet, and the circumstances which determine a variation in the quantitative demands of the system upon these substances. The nutritive demands of the human organism, from the period of infancy to that of adolescence and from the latter to that of maturity and decline, are subject to varying fluctuations. Again, different degrees of bodily activity, both physical and psychical, during sleep and the waking state, thermic and climatic influences, body weight and size, and finally various pathologic conditions, all make definite nutritive demands upon the system. For instance, in infancy there is more nutriment required, estimated per kilogram body weight, than during the period of maturity; the body weight and size has an influence, as we have already pointed out, in so far that a smaller organism requires relatively more nutriment than a larger one; during sleep or absolute rest, compared with the waking state, the albumin metabolism remains unchanged, while the fat and carbohydrate consumption is reduced; bodily exercise is accompanied by an increased carbohydrate and fat consumption, while the albumin metabolism remains uninfluenced. Heat and cold affect the organism differently—increased body temperature raises the total carbohydrate and fat consumption, while the reduction of external temperature increases, and an increase of external temperature reduces, both the fat and carbohydrate metabolism.

Finally, in pathologic conditions, such as fever, dyspnea, anemia, diabetes, Bright's disease, icterus uric acid diathesis, etc., various nutritive abnormalities are discernible, and it behooves us at this point to determine the normal nutritive mean of the organism and its practical application to pathologic conditions. In this way we shall be enabled to logically appreciate the dietetic demands in pathologic conditions and estimate the applicability of artificially digested foods to the dietary of invalids. We indicated in our foregoing remarks that the preferable diet for a normal individual is one consisting of certain quantities of albumin, fat and carbohydrates.

Determined by methods which consisted in estimating the nitrogen and carbon output in individuals subsisting upon an ordinary indefinite diet, it was originally estimated that the average individual of 70 kilograms—154 pounds—body weight, at rest and during moderate and severe physical labor requires for every twenty-four hours, 100 to 140 grams of albumin, 50 to 100 grams of fat and 400 to 500 grams of carbohydrates. Practical observation has shown that some individuals subsist upon as little as 75 to 80 grams of albumin in twenty-four hours, and experimentally these figures can be materially reduced for a considerable length of time, as the writer showed in a series of experiments covering a period of 33 days.[3] In ordinary cases, however, unless prompted by some particular reason to materially reduce the albumin quantity, it will be preferable to adhere to the 90 to 100 grams of albumin ration for the average individual at rest or during light exercise. Figured in calories, the average individual requires during absolute rest from 30 to 34 calories per kilogram body weight, during light exercise 34 to 40, for a medium amount of work 40 to 45, and during severe labor 45 to 60 per kilogram body weight, for every twenty-four hours.

A diet consisting of 100 grams of albumin, 50 grams of fat and 400 grams of carbohydrates would equal: Albumin 100 grams × 4.1 = 410 calories; fat 50 grams × 9.3 = 465 calories; carbohydrates 400 grams × 4.1 = 1640 calories—a total of 2515 calories. This number of calories represents a sufficient amount of heat or food, for an individual weighing about 74 kilograms, or 163 pounds, at rest. To further elucidate this method of estimation I append a diet list, which I used in a series of experiments made upon myself[2].

Materials.	Quantity	Albumin. (Nitrogen 6.25.)	Carbohydrates.	Fat.
Meat	75 grams	15.40	....	1.33
Rice	200 "	12.36	149.60	0.66
Potatoes	225 "	5.49	45.00	....
Bread	200 "	17.92	120.00	....

Materials.	Quantity	Albumin. (Nitrogen 6.25)	Carbohydrates.	Fat.
Starch	70 grams.	0.28	69.72	....
Eggs	50 "	6.27	....	6.05
Milk	150 "	5.60	7.39	6.75
Sugar	40 "	....	40.00	....
Butter	50 "	0.43	....	....
Beer	700 "	3.67	62.51	....
Tea	760 "	0.58	....	....
		67.80	494.22	60.49

Albumin $67.80 \times 4.1 = 277.98$ calories; carbohydrates $494.22 \times 4.1 = 20.26$ calories; fats $60.49 \times 9.3 = 562.56$ calories—a total of 2866.84 calories.

In the foregoing table the quantity of fat, albumin and carbohydrates is accurately accounted for as is also the total caloric value. The number of heat units, 50.22 per kilogram body weight, is greater than was really necessary, but I chose this number for the reason that I was reducing my albumin ration far below the usual quantity, as I determined by a great number of total nitrogen estimations while on an indefinte diet.

ARTIFICIALLY PREPARED OR PREDIGESTED FOODS.

This brings us then to the actual consideration of the subject of artificially digested foods, and their application to the diet of invalids.

Until 1843, when Graves published his observations upon the diet of fever patients, there existed a dictum in the practice of medicine, which read, that to successfully treat fever patients the diet must needs be reduced to a minimum quantity, and this was successfully accomplished by resorting to cereal water and various broths, which were practically destitute of nutritive value. Following the writings of Graves, in which it was urged that "fevers be fed," the observations of Chossat on the effect of inanition were published, and these two writings then, in conjunction with the experimental observations of Liebig, Voit, Pettenkofer, et al, acted as an incentive to the research upon which our present knowledge of invalid feeding is founded.

Although as early as 1752 Reaumer and Spallanzani discovered the digestive action of gastric juice, it was not until 1824 that Prout discovered the gastric hydrochloric acid, and 1850 that Lehman first applied the term of peptone to the products of albumin digestion. The diastatic action of saliva was not discovered until 1831, although Payen had discovered grain diastase thirty-six years previous to this time.

We have evidence that in ancient times grain water was added to milk to render it more easily digested, and other methods were resorted to in attempting to make food more acceptable to invalids, yet the first important attempt to produce artificially prepared foods was made subsequent to the discoveries which we summarized in the preceding pages. As in other matters pertaining to nutrition, Liebig was a pioneer in the department of artificially prepared foods. Liebig's efforts resulted in the production of these two foods which bear his name: 1, Liebig's extract of beef,[4] known, we dare say, to every civilized race; 2, Liebig's infant soup, which while it is remembered by but few to-day nevertheless deserves the distinction of being the preparation which has given rise to the almost countless numbers of so-called baby foods.

When one considers the havoc which many of these improperly prepared invalid and baby foods have occasioned and the misuse to which numerous really praiseworthy preparations have been subjected, the thought involuntarily arises as to whether it would not perhaps have been far better had the idea of artificially preparing foods for invalids and babies never occurred to any one. The subject of the feeding of artificially prepared foods is in the same deplorable condition as that of nutrition in general, but whereas ignorance and neglect of the subject of nutrition, as applied to feeding the average individual and using the term in a general sense, affects simply healthy or somewhat indisposed individuals, lack of proper knowledge to correctly adjust the administrations of artificially prepared foods affects both the helpless infant and the invalid, who really are in need of proper nourishment.

The medical world is justified in insisting that the manufacturer produce an artificially prepared food which answers the requirements of the nutritive demands of invalids. Further, the manufacturer should be compelled to print upon the package of each preparation of artificially prepared food an exact quantitative and qualitative analysis. This is a duty which the manufacturer owes to the medical world, and the duty which the latter owes to the manufacturer is that it sufficiently comprehend the principles of nutrition, thereby insuring the rational application of reliable preparations to the dietary of invalids. With these points observed it simply remains to be determined, in selecting an artificially prepared food, whether it be palatable to the patient and whether it possess the nutritive and therapeutic value required of it.

In selecting an artificially prepared food for an invalid, we are guided by the same principles of nutrition and metabolism as in feeding an individual in health. An invalid, like a healthy individual, requires a definite quantity each of albumin, fat and carbohydrates to furnish the necessary total caloric demand of the organism. We find a deviation from the above statement in certain pathologic conditions, in which it is necessary to reduce the quantity of one nutrient principle and substitute in its place another. I have reference to the reduction or entire withdrawal of carbohydrates in diabetes, the reduction of albumin in uric acid diathesis, etc. Irrespective of a reduction of particular food principles, the total caloric supply must remain unaltered or at least as little changed as is compatible with the condition of the patient. The dream of the medical profession, from the very dawn of the science of nutrition, has been to prepare an artificially digested food which would relieve the gastro-intestinal tract of its usual digestive labor, but, like the illusion of an elixir of everlasting youth, it has resulted only in idle and futile search.

With the newly acquired knowledge of some of the more pronounced phases of digestion, it is comprehensible why the trend of scientific aim should have led experimenters and clinicians in this direction. The artificial conversion of albumin, fat and carbohydrates into their respective end products has, it is true, been accomplished, but, despite this, the subject of the feeding of artificially digested foods is still far from being solved. While the artificial preparation and dietetic application of fats and carbohydrates have given fairly satisfactory results, the same can not be said of predigested albumin, since peptones and albumoses have proved to be stubborn and unyielding in the extreme.

It is not so many years ago that Voit, along with Bruecke and other celebrated physiologists, supported the old view of Tiedeman and Gmelin, according to which peptone was considered to be a decomposition

4. Proust as early as 1821 produced meat extract, but the credit of the practical manufacturer of it really belongs to Liebig.

product and one that could not be regenerated into albumin. It was thought that the peptone resulting from the digestion of albumin in the gastro-intestinal tract was absorbed by the circulation as such, and was oxidized in the system in a similar manner to carbohydrates and fats, while the albumin necessary to rebuild the wasted tissues of the organism was thought to be dependent upon the absorption of unaltered albumin from the gastro-intestinal tract. Lehman, on the other hand, contended that the conversion of albumin into peptone was a definite physiologic process, which served the purpose of rendering the latter more easily absorbed, to again be converted into albumin in the circulation. The great authority of Bruecke, however, had its influence, and as late as 1877 peptone was looked upon as being a product of decomposition. Further exact experimental research has indeed proved that many albumins, such as serum albumin, egg albumin, acid albumin and globulin, may reach the circulation without first undergoing peptonization, but it has also been demonstrated that the end products of albumin digestion, instead of being products of decomposition, are reconverted into albumin in the mucous membrane of the gastro-intestinal tract to circulate as such in the system, which fact definitely disposes of the older contention of Voit, Bruecke and others. Two or three years previous to this period the first peptone feeding experiments were instituted, and, while the results of several experimenters made it appear very probable that peptone, so-called, did possess nutritive worth, the proof was not sufficiently conclusive to prevent Voit, as late as 1881, from offering experimental data in support of his earlier contention. Up to this time peptone was considered a simple or elementary compound, but the famous investigations of Kuehne and Chittenden and other of his pupils proved that peptone was really a mixture of many different substances and that the so-called peptone—preparations of manufacturers—consisted principally of albumoses, bodies intermediate between albumin and true peptone.

Several experiments instituted with albumoses and pure peptone apparently proved that the former could serve as a substitute for albumin, while peptone usually acted as a violent irritant, causing vomition and diarrhea. Following these preliminary observations it was then finally proved that a number of preparations, consisting chiefly of albumoses, together with varying quantities of true peptone and insoluble albumin, could be substituted for the ordinary unaltered albumin, such as is contained in the daily food ration. Still more convincing and decisive are the experiments made with pure albumoses, which prove that their nutritive worth is equivalent to unaltered albumin, while anti-peptone, resulting from pancreas digestion at least, seems to be destitute of this power of substitution.

With this problem of the nutritive role of peptone and albumoses fairly well decided, the question arises whether artificially digested albumin is really applicable to the diet of invalids. We have seen that true peptones have not given satisfactory results as dietetic agents, and, if we bear in mind the comparatively recent discovery that true peptones are formed only in very small quantities in the stomach and that albumoses very likely represent the digestive products which enter the circulation, it becomes evident why concentrated quantities of peptone disagree with patients in the manner noted above. Dismissing, therefore, the idea of utilizing pure peptone as a dietetic agent, and recognizing the clinical and experimental evidence of the nutritive worth of albumoses, we must further ask ourselves what advantage we hope to obtain and what effect we really produce by the feeding of artificially digested albumin. To begin with, most of these preparations have rather a disagreeable taste, which is a disadvantage in a food, making the addition of either meat extract or some other taste-disguising agent necessary. Further, contrary to the general belief, predigested albumin does not possess a higher nutritive worth than ordinary native albumin.

A claim which is often emphasized by manufacturers and accepted by many as being true, is that artificially digested albumin is more easily absorbed than native albumin. But here also abundant experimental and clinical data disprove these claims. The worth of an artificially digested food like that of an ordinary foodstuff is estimated by the manner and degree in which it is utilized in the gastro-intestinal tract.

Let us begin with the stomach. We are in possession of data which prove that the rate of peptone absorption from the stomach is extremely slow and considerably slower than either alcohol or the different forms of sugar. Further, it has been shown that a solution of artificially digested albumin is not absorbed more rapidly from the stomach than a nutritive equivalent of powdered meat measured in calories. The absorptive maximum of the stomach, as one would expect, bears a relation to its degree of digestive activity, and, beyond this degree, the absorption can not be forced. In regard to the intestinal absorption of artificially digested albumin, our experience is as unsatisfactory as in regard to the gastric absorption. Ellinger, for instance, has shown in some comparative tests with meat and somatose that, when each was separately given in quantities representing 8.92 grams of nitrogen, with meat the excreta contained but one gram of nitrogen, while with somatose they contained 10.6 grams of nitrogen. By still another method, that of estimating the degree of intestinal decomposition as expressed by the urinary sulphuric acids, it has been shown that somatose, a representative artificial albumin product, possesses no advantage as a nutrient over native albumin.

It will be seen, therefore, that the supposition that peptones and albumoses are more readily and more perfectly utilized than native albumin does not bear the test of careful investigation. Closely linked to this idea is the supposition that predigested albumin taxes the digestive functions less severely than unaltered albumin. This, like the other statements, is erroneous, for it is clear that the expenditure of energy lies in the secretion of the digestive fluid, not in the digestion of food after the digestive fluid has been secreted.

One might be led to contend that artificially digested albumin does not excite the glandular activity to the same degree as does native albumin. But here again we are confronted with investigations which show that the gastric acid secretions, as determined by exact chemical analysis, may be as great as and even much greater in the case of albumoses and peptones than in the case of unaltered or native albumin.

The second pronounced expenditure of energy of the digestive organs, that of motility, by which food is propelled onward from the stomach into the intestines, is as great, as we have already seen, in the case of predigested as in the case of native albumin. In particular pathologic conditions of the gastro-intestinal tract the results of the application of artificially digested albumin are not materially different from those which have been already mentioned. If we group the distinctive chemical fea-

tures of the stomach cases, we find that in one class we may have an absolute absence of acid, and in another class a normal or excessive quantity of acid. Between these two extremes we find cases with varying degrees of acidity, which we need not here define more particularly. In addition to the acidity of the stomach, the motility is of the greatest importance, for it is this muscular mechanism which determines the onward propulsion of food from the stomach into the intestines. Irrespective of the acid condition of the stomach the motility may be abnormally accelerated, slowed or entirely inhibited. It is clear that in cases of absolute cessation of motility, resulting, for instance, from a dilatation, dislocation or a pyloric stenosis, it is as useless to introduce artificially digested albumin into the stomach as it is to resort to native albumin. So also, when the motility and acidity are normal it is unnecessary to resort to artificially digested albumin. Even when the hydrochloric acid and peptone digestion is much reduced, or entirely absent, as in acute and chronic fevers, true gastritis, etc., the unaltered albumins may be perfectly utilized, as is clinically seen every day, and which both the clinical and experimental cases of total gastric extirpation have conclusively proved. It may be remarked, however, that certain particularly selected cases of an acidity with normal motility do not offer any direct objection to the use of artificially digested albumin, provided it does not prove too irritating to the gastro-intestinal canal.

Large quantities of many of the artificially digested albumins usually act as a laxative, and it is this action which recommends its moderate use in some cases or absolutely condemns its use in others. The great majority of artificially digested albumins are to be looked upon as gastro-intestinal stimulants, rather than nutrients which can be substituted for the maximum requisite quantity of albumin for any great period of time. Peptones and albumoses may be temporarily employed alone or as adjuncts to other foods in cases where there exists either a repugnance to ordinary food, where the mastication of food is difficult or impossible, or where there exists an incomplete mechanical obstruction in the esophagus, and where it is necessary to relieve the stomach entirely from mechanical irritation. In gastric ulcer, hyperacidity and in all cases where an over-production of the gastric secretion and hydrochloric acid is to be avoided, irrespective of the condition of motility, the artificial albumin preparations are not to be used. The other contraindications have already been referred to and need not be gone over again.

The subject of the feeding of artificially prepared fats and carbohydrates, while not exactly identical with that of predigested albumin, is nevertheless very similar to it, and many of the difficulties encountered in connection with the predigested albumins are also common to both the carbohydrates and fats. Various attempts have been made to increase the ordinary rate of fat absorption by mixing it with foodstuffs and chemicals and by emulsifying it in various ways. It has been found, however, that when the motility of the stomach is unimpaired and the pancreatic and biliary secretions are normal, the absorption of unaltered, native fat, such as is contained in milk, cream, eggs, butter, etc. is very satisfactory indeed. It has been shown that as high as 300 grams (about 10 ounces) of fat, representing 2790 calories, may be absorbed from the intestinal canal in twenty-four hours.

Practically no progress has been made in the direction of fat alimentation and this subject is now generally looked upon as belonging to impenetrable territory. However unpromising as the present outlook may appear for an advance in this problem, especially in conditions of general marasmus and in hepatic and pancreatic difficulties, the future may, nevertheless, offer a means for the eventual solution of the difficulty.

The logical, artificial conversion of starch into sugar for specific, dietetic purposes dates from the time when Liebig first prepared his infant's soup, although the empirical dextrinization and saccharification of starch has been practiced from time immemorial. When native starch is introduced into the mouth it undergoes a chemical conversion into maltose. Usually, however, this conversion is not completed until it reaches the stomach, and not even then if the contents of the stomach are decidedly acid. In the latter case the conversion is not completed until it reaches the small intestine. To insure the complete conversion of unaltered starch into sugar and the absorption of the latter into the circulation, it is necessary to prepare it in a very finely powdered form. Various preparations in which this precaution has been taken are to be found on the market and give very satisfactory results. The starch contained in these preparations may either be converted into dextrin by heat during their special preparation for the invalid, or into maltose by some particular malt solution or diastase. Investigation shows that from 500 to 700 grams of unaltered starch, representing 2050-2870 calories, may be almost completely converted into sugar and absorbed by the gastro-intestinal canal in twenty-four hours.

In infants in whom, as is now generally recognized, the diastatic functions of the salivary and pancreatic glands are but imperfectly developed, it is necessary to first convert the starch into dextrin and maltose, or preferably entirely into maltose in cases where it is thought advisable to feed with artificially digested foods of this variety. In adults good results are obtained from these foods in various salivary, gastric and intestinal disturbances in which unaltered starch is not properly utilized in the organism. Both dextrin and sugar are absorbed by the stomach as well as by the intestines, and, as one would expect, the diffusibility and absorptive rate of sugar is considerably greater than that of dextrin.

Just as in the case of the ingestion of predigested albumin, much depends upon the motility and absorptive condition of the stomach as to whether or not the converted starch or native sugar is properly utilized. Large quantities of converted starch or native albumin induce very decided gastro-intestinal irritation with fermentation and diarrhea. Although the ingestion of enormous quantities of starch never induces in the healthy individual an appearance of sugar in the urine, quantities of dextrose ranging from 100 to 250 grams are sufficient to induce a decided transient glycosuria. In the rational application, however, of dietetic preparations containing native sugar or converted starch, this undesirable effect is hardly to be feared. I simply wish to emphasize these circumstances to show the physiologic limitations of forced carbohydrate alimentation.

At times cases may arise in which it is desirable to substitute honey, cane sugar, milk sugar, glucose or fruit sugar for either native or predigested starch, and, when properly selected and carefully applied, these aid very materially in increasing the total caloric value of the diet of the invalid. To this class we may add the various malt preparations, which, in connection with their diastatic properties, possess a certain nutritive value.

On the whole, artificially prepared starches given alone or mixed with specially prepared milk foods have given good results in my hands. They offer a convenient form in which to exhibit this class of dietetic preparations, and, as a change from the various other foodstuffs, are generally very much relished by patients.

It is not my object, nor would it here be in place, to attempt a criticism on the value of these and other especially prepared foods in infant feeding. When used with judgment and discretion they undoubtedly often render valuable service; when they are indiscriminately prescribed, however, they give correspondingly bad results. From all this it will be seen with what difficulty every attempt is beset which strives to lessen the labor of the gastro-intestinal canal by the exhibition of artificially digested foods.

Unfavorable as this criticism may appear to the subject of artificially prepared albumins, I trust that it will not be construed as being intended as a reflection upon the efforts of manufacturers of artificially prepared foods. There are many who are honestly and sincerely interested in the production of a superior dietetic preparation and to them this is offered as a friendly criticism, which I hope may act as a stimulus to further efforts to produce a perfect artificially digested food—one free from the untoward secondary actions we have discussed. Much remains to be said on this subject, and it might have been of interest to have included a careful analysis of every class of artificially prepared foods in our discussion. Lack of time and space did not, however, admit of this, and I dwelt upon the albumins particularly, for the reason that they are so difficult of application and so universally misunderstood.

THE SOMATIC SIGNS OF BRAIN SYPHILIS.*

HUGH T. PATRICK, M.D.

Professor of Neurology, Chicago Policlinic; Clinical Professor of Nervous Diseases, Northwestern University Medical School; Neurologist to the German, Passavant, Maurice Porter and Wesley Hospitals.

CHICAGO.

This paper takes no cognizance of inherited syphilis or of the degenerative diseases in some way caused by specific infection, but is limited to the signs of histologically definable specific invasion of the brain.

Before entering upon the details of my subject, I beg indulgence while I enunciate half a dozen postulates relating to the clinical history and more general symptomatology of cerebral lues, which seem to me so important as to be inevitable as a preface.

1. Brain syphilis is most frequent in the first year after infection, next most frequent in the second year, less frequent in the third year and so on, about 50 per cent. of all cases occurring within three years after the primary sore. After ten years of quiescence, therefore, the appearance of cerebral syphilis is exceptional.

2. In reaching a diagnosis of a brain case, absence of a history of specific infection should have no weight in the case of women, and in the case of men relatively slight importance.

3. Syphilis of the brain is not synonymous with gumma. I do not know how the myth became current in the profession, but the average practitioner works in the obscurity of the tenet that brain syphilis means gumma and is utterly oblivious of the fact that this is the least frequent form of cerebral specific lesion.

4. Most frequently brain syphilis means syphilitic arteritis. Next in frequence come syphilitic meningitis and syphilitic infiltration of the cranial nerves, while a gumma comparable to a brain tumor is least frequent.[1]

5. Paralysis from brain syphilis (excluding paralysis of the cranial nerves) is most frequently caused neither by the pressure of a gumma nor by hemorrhage, but by thrombosis due to syphilitic arteritis.

6. Consequently, many cases of syphilitic paralysis are no more amenable to treatment than are those of cerebral thrombosis due to ordinary arteriosclerosis and atheroma (influence of age excepted), which means that the important symptomatology is that which precedes and presages paralysis, because it is at such time that prompt treatment obtains brilliant, almost miraculous, results.

7. Syphilis is never a "system disease." As the Anglican sage, Sir William Gowers, puts it: "As a general rule, if we find certain structures of common function selected for isolated impairment from among others of different function, we may be sure that we have not to deal with a true specific process."

In what follows mention is made only of those symptoms deemed by the writer to be most important by reason of their frequence or diagnostic importance or because, having been overlooked or forgotten by the average practitioner, they need to be called to his attention. No categorical enumeration of symptoms is possible in compass less than a brochure and a concise grouping of them is impracticable because the only systematic thing in the symptomatology of brain syphilis is the utter want of system, which suggests the first trait.

1. *Lack of Type.*—So strikingly consistent is brain syphilis in the production of apparent inconsistencies, that any brain case having an odd mixture of psychic and somatic disorder, a sequence of signs illogical as regards either time or localization, or a bizarre appearance, disappearance, reappearance, amelioration and aggravation of symptoms, should at once awaken suspicion of lues. For cerebral syphilis nothing is impossible. Insomnia, somnolence or an alternation of them; pain without anesthesia, anesthesia without pain or painful anesthesia; spasm without paralysis, paralysis without spasm or the two combined; monoplegia, paraplegia, hemiplegia, crossed paralysis, single or multiple cranial nerve paralysis, and any imaginable grouping of them; focal signs rivaling in neatness the most dexterous work of experimental pathology or a hodge-podge of symptoms carrying only confusion to the brain anatomist and physiologist; half-way manifestations, scarcely inflammatory, more than neoplastic; these are a few of the tricks of specific lesions within the cranium. A few years ago, when the London police found the remains of a mysterious murder, the body showing inexplicable mutilations, they said "Jack the Ripper." When the neurologist meets a brain case comformable to no rule, abounding in inconsistencies, ignoring anatomy, a clinical outlaw, he is very apt to say "brain syphilis."[2]

2. *Headache.*—In about 75 per cent. of all cases of cerebral syphilis headache is present. Notoriously nocturnal in its exacerbations, it may be vesperal, or even

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

1. The foregoing is not to be understood as an attempt to controvert the fact that nearly all syphilitic lesions are histologically almost identical, i. e., granulomata—cellular accumulations—but merely as a protest against the baseless popular impression that brain syphilis simply means syphilitic tumor of the brain, and that the symptomatology of brain syphilis is simply the symptomatology of brain tumor.

2. The only organic disease which can compete with syphilis in polymorphism, fluctuation and melange of types is multiple sclerosis.

diurnal and allow the patient to sleep all night. It is usually severe. The location is unimportant. In the beginning, although the lesion is constant, the headache is not; it may remain away for days or even weeks at a time and thus be mistaken for migraine or for malarial, infectious or stomachic cephalalgia. As the case advances, however, it becomes more continuous and may finally keep the patient in agony day and night. If occipital, the pain not infrequently radiates down one or both arms, even to the fingers, and may be accompanied by rigidity of the neck. Most frequently, but not always by any means, some part of the head is tender to percussion or pressure.

3. *Transient Attacks.*—These include every sort of fit, from the slightest to the most severe. They may be: 1. Attacks of dizziness, trifling or tumultuous. 2. Attacks scarcely to be distinguished from syncope. 3. Momentary losses of consciousness, exactly like petit mal. 4. Localized numbness or tingling—one side of face, one hand, etc. 5. Spasms, from the most trivial and restricted twitching to generalized violent convulsions. Typical Jacksonian fits are far from rare. Oppenheim says that the convulsions of syphilis are distinguished by their violence and frequency. My own experience is that while they are apt to be frequent and at times prolonged, the spasm is more often slight, not violent.

Some of these fits are apoplectoid rather than epileptoid. The patient suddenly has a seizure, with or without loss of consciousness, with or without spasm, but attended with loss of power more or less marked, more or less transient. Later, of course, such an attack may be more grave and the paralysis permanent. Epilepsy or apoplexy between 20 and 40 should always awaken suspicion of specific disease.

4. *Cranial Nerve Paralysis.*—Frequent, striking, imperative in their indications are palsies of the various cranial nerves, and of these oftener involved than any others are those pertaining to the eye. I need only mention that Alexander's statistics showed 72 per cent. of unilateral paralyses of the third nerve to be due to syphilis, and Uhtoff concludes from his observations that only 15 per cent. of all cases of cerebral lues are without eye symptoms. I should say that, in the absence of traumatism, at least 90 per cent. of all cases of ocular paralysis in adults are caused by brain syphilis, locomotor ataxia, general paresis, and brain tumor, and of these by far the most frequent causes are locomotor ataxia and syphilis—diseases that may usually be distinguished at a glance. Of primary optic atrophies more than 90 per cent. are certainly due to tabes, syphilis and general paresis. Tabes causes the most. Choked disc and optic neuritis may be mentioned here. They are not so very frequent. When present they are almost pathognomonic of intracranial organic disease, but serve in no way to distinguish luetic from other changes.

In this connection, too, I may speak of disturbances of the visual field. The long course of the visual tracts, almost from pole to pole of the brain, makes them liable to injury by lesions of various location and, besides, the exposed position of the optic nerves and optic tracts at the base causes them to be involved with frequency. Currently, the visual field is examined far too infrequently. Alterations in the field may be quite unknown to or erroneously interpreted by the patient and thus escape knowledge of the physician unless systematically looked for. Besides affording indubitable evidence of organic disease they may, alone or in conection with other signs make the localization easy.

All of these ocular signs are apt to have the inconsiderate disregard for anatomical facts and established types before spoken of. There is no necessary correspondence of pathological findings to clinical picture. The whole third nerve may be embedded in a gummatous meningitis and yet only part of the fibers suffer, while complete paralysis in all its branches may depend upon almost undiscoverable changes. Unaccountable alterations in the visual field, blindness without changes in the fundus, appearance and disappearance of symptoms so sudden as to suggest only functional disease are some of the many manifestations showing the capricious character of brain syphilis.

Less frequently than the ocular nerves, but still quite often, are the fifth and seventh attacked, and with the latter the auditory is very apt to be involved. The first sign of involvement of the fifth is paresthesia or pain in the distribution of one of its branches. As the disease progresses these irritation symptoms spread to other branches. With the pain, maybe shortly preceding or following it, comes impairment of the tactile sense, the patient then presenting anesthesia dolorosa—a complex almost invariably due to organic disease of the nerve trunk. The fifth is affected on one side only. Paralysis of the seventh is, of course, of the peripheral type, and may affect both nerves, either alternately or simultaneously, although unilateral trouble is the rule. Lesion of the auditory, causing tinnitus, deafness, aural vertigo, or all three, is rare without implication of the facial as well.

Cranial nerves below the eighth are affected with less frequency, but none are exempt. Dysphagia, partial paralysis of the tongue, alteration in the pulse rate, laryngeal paresis, partial paralysis of the sterno-mastoid and trapezius muscles and cerebellar symptoms, alone or in combination, are produced when syphilis invades the posterior fossa of the skull. In case the basilar artery and its branches bear the brunt of the attack, materially interfering with the bulbar and pontine circulation, the grouping of cranial nerve signs will be that of bulbar paralysis—the glossolabio-laryngeal complex.

Before leaving the subject of cranial nerves I can not refrain from again calling attention to the extreme irregularity of the voicings of syphilis and to the value of this lack of system as a diagnostic pointer. While cerebral lues may affect the cranial nerves as would any basilar disease, invading those close together and causing gradually increasing symptoms as the disease progresses, it more frequently acts in a more erratic way. One nerve on one side and quite a different nerve on the other; one anterior and one posterior nerve on the same side; paralysis of one nerve, disappearance of this paralysis and then paralysis of another, nearby or at a distance; paralysis of some fibers of one nerve and then serious involvement of another without the first growing any worse; these are some characteristic vagaries.

5. *Addition of Spinal-Cord Symptoms.*—This is perhaps as good a place as any to speak of the complications of cerebral with spinal syphilis. While it savors of Erin to speak of spinal symptoms as part of the signs of brain disease, it is a fact that syphilitic disease of the cerebral meninges does often spread to the spinal membranes. When, therefore, to the characteristic signs of cerebral disease are added symptoms pointing to disease of the cord or its membranes, the diagnostician is materially aided in coming to a conclusion.

6. *Impending or Accomplished Thrombosis.*—As be-

fore stated, arteritis or arterial cellular infiltration is the most frequent form of brain syphilis. Syphilitic meningitis must inevitably compromise arteries and veins and even a gumma may disclose itself principally by the invasion of adjacent vessels. Obviously, then, many of the signs of cerebral lues will be those caused by local abnormalities of circulation, and they resolve themselves almost entirely into the signs of impeded circulation and arterial occlusion. Most of these signs have already been mentioned, but it seems advisable to review them from the standpoint of arterial lesions. Indeed, it is well to frequently remind ourselves that although the symptoms of cerebral syphilis are due entirely to injury of nerve cells and fibers, the disease is not primarily one of the nerve elements at all, but of extra-neural tissues—arteries, veins, membranes, nerve sheaths. To involvement of arteries at the base of the brain, Heubner attributed most of the intellectual and mental symptoms of brain syphilis; a great many of the early and late somatic signs are directly attributable to partial or complete occlusion of arteries. Among the earlier, besides headache, are transient attacks of dizziness, of numbness of one hand, one foot, one side of the face or tongue; transient aphasia or paraphasia, alalia or dysphagia; temporary diplopia, ptosis, or dilatation of one pupil; sudden weakness of one hand or leg, or partial hemiplegia which rapidly disappears; localized clonic spasm or twitching —all of the foregoing without loss of consciousness. As the disease is never confined to one arterial twig and very often affects the nutrient vessels of parts differing widely in function, these early, so-called premonitory signs may present peculiar associations. Dilatation of one pupil and paresthesia of a hand, numbness of the left face and clumsiness of the right hand, partial aphasia and slight dysphagia, diplopia and weakness of one leg, may be noted as illustrations.

Then there may be a general neurasthenic and myasthenic condition with insomnia or moderate somnolence without focal signs. Later come more pronounced symptoms; the dizzy spells become brief losses of consciousness, the pareses are less transient and disorders of speech more enduring. It is only one step more to a grave apoplectic attack from thrombosis of a considerable artery. If the vessel belong to the cortical circulation and be not too large, such an attack may be rapidly recovered from, but if such considerable vessel supplies the basal ganglia or cranial nuclei, the disability is permanent, and if the artery be a very large one of any part the result is permanent disability or death. As in thrombosis from lesions other than specific, a complete hemiplegia may occur without loss of consciousness, or with only moderate confusion or somnolence. This is not true of hemorrhage. In many cases the hemiplegia comes on in such a way as to clearly indicate either temporary arrest of circulation or partial occlusion of an artery followed by its complete closure or, what I believe to be more frequent, thrombosis of a small branch followed by occlusion of adjoining branches or of the main artery by extension of the intra-arterial clot. Such a course of intracranial proceedings is evidenced by restricted or very slight paralysis, followed in some hours or days by more extended or complete disability.

I believe that largely to arterial invasion is to be attributed another of the frequently observed features of brain syphilis, viz., progress by separate steps or increments. Without appropriate treatment, cerebral syphilis progresses more or less rapidly for the worse, but never uniformly, always by fits and starts, often with intercurrent improvement. Not rarely these increments affect different parts. A small artery becomes so badly damaged that circulation in it is stopped. Before a second calamity takes place in that immediate vicinity, another arterial twig at some distance suddenly goes out of commission, adding one more sign to the clinical picture, while that caused by the first stoppage may be improving.

Of material assistance in some of the earlier cases are increase of the deep reflexes and incoördination. The patient may make complaints such as indicate merely functional disease and the physician may detect neither anesthesia nor motor impairment, but careful examination may show increased deep reflexes on one side, as compared with the other, or slight incoördination in finer movements.

7. *Peculiar Stupor.*—While not wishing to trench upon the topic of Dr. Dewey, which none can handle so well as he, I would slight my own subject were I not to mention the somnolent, semi-stuporous condition which occurs more frequently in cerebral lues than in any other brain disease. Combined with one or more of the foregoing somatic signs it is well-nigh pathognomonic and even alone is strongly suggestive. In this condition the patient seems to be almost comatose, but can be roused and when once awake is practically rational, although he may be decidedly irritable, not to say bellicose. The condition was long ago likened to a drunken state; after being roused and responding to enquiries, the patient at once lapses into his previous stupor. Without fever and preceded by or combined with severe headache, the symptom means grave organic brain disease, in numerous instances, syphilis.

8. *Fever.*—Cerebral syphilis may be considered to be an afebrile disease. Fever is exceptional unless pons or medulla oblongata be involved, when rise of temperature may be slight or considerable. In some cases the fever has seemed to me to be caused by bad condition of the gastro-intestinal tract and absorption therefrom.

9. *Vomiting.*—This occurs in many cases, more frequently when the posterior fossa is invaded and when a large gumma or extensive meningitis is present. Such emesis, although of cerebral causation, may take place only when the stomach is full and may be determined more by one sort of food than another. Nor should it be forgotten that cerebral vomiting is not necessarily projectile.

10. *Polydipsia, polyuria* and *polyphagia* are not unusual results of brain syphilis, the last being the least frequent.

11. *Insomnia* is not rare, aside from the inability to sleep on account of headache, and besides vertiginous attacks, constant dizziness may be present.

THE PSYCHOSIS IN CEREBRAL SYPHILIS.*

RICHARD DEWEY, A.M., M.D.
WAUWATOSA, WIS.

When I came recently to consider attentively the subject assigned me in this discussion, I was so doubtful as to the production of anything of value that I asked the chairman to excuse me, but as both the present chairman and the chairman of last year renewed their request, I have complied with their wishes as well as possible.

When one attempts to lay down the lines upon which

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

the subject should be treated, several questions arise which require to be first taken into consideration. One is the evidence of syphilis. Another, the very frequent existence in these cases of causes other than syphilis which have their share in determining the mental state—such as alcoholism; senile changes; arterial disease; kidney and heart disease and tumors, of non-specific origin.

If the rule were made and followed of first catching your specific lesion and then excluding alcoholism and non-specific vascular changes, etc., a portion of the foundation for much writing on this subject would crumble away. On the other hand, syphilis is not and can not be excluded, even when neither history of it nor somatic signs are attainable. Fournier states that syphilitic disease of the nervous system is found more frequently than are the external signs of syphilis. Berkely attributes to syphilis all cases under 40 of hemiplegia or monoplegia and mental disturbance, where cardiac and renal disease were not found; also obscure dementias between the years of 25 and 40. This method of reaching a diagnosis must have an element of uncertainty, though doubtless in a general way the deductions are correct. There are probably as many cases in which syphilis is concealed or remains undiscovered as there are incorrectly diagnosed, but striking a balance by this method is not satisfactory for our present purpose.

It would seem that the reasoning adopted in many cases was something like this: "Here is a case of organic brain disease, coarse or fine, paresis, hemiplegia, monoplegia, suspected tumor or vascular lesion. It is antecedentally and consequentially probable the patient has had syphilis; therefore this is cerebral syphilis." Then the mental manifestations are sometimes taken up and treated as due to syphilis without positive evidence either before death or postmortem, and perhaps without considering whether the same mental states are not closely paralleled by cases certainly non-specific, or whether the findings may not be due to general and not specific causes, even though syphilis be present.

One instance of syphilitic psychosis that may be mentioned here is the mental state found in syphilitic tumor of the brain; but can any one distinguish between the psychopathic effects of a specific and a non-specific tumor? Again, how are the arterial disease due to syphilis and that due to other causes to be differentiated in their mental phenomena? Consider in the same way the effects of edema and intra-cranial pressure, with interruption or irritation of tangential tracts; also those of the various toxins. These morbific agents must destroy or derange the "cytopsyche" and the "histopsyche," assumed by some German writers to preside over the cell and tissue life (and I believe countenanced even by Haeckel); but the relation, if any, between the unconscious soul ascribed to the units of structure and the conscious soul that has for its instrument the entire brain, is something as yet beyond scrutiny. The cœnesthetic sense which is essential to soundness of mind is impaired in all psychoses. The association tracts belonging to the various brain centers are interrupted by syphilitic connective tissue overgrowth, or by poison or malnutrition, from primary degeneration of neurons, but how does this differ from the disease or destruction of association tracts from other brain changes, or from neuron degeneration from other poisons?

Berkely[1] in his recent work states: "Lues never directly affects nervous tissues." Moebius, as quoted by Bannister,[2] treating paresis as a syphilitic toxin disease, asserts: "There is only one kind of general paralysis and only those have it who have previously had syphilis." Is general paralysis a psychosis of syphilis simply? If so, we have at least one syphilitic form of insanity, but Moebius' claim is by no means fully substantiated. Probably as many pathologists would be found to deny as there are to affirm that tabes and general paralysis are exclusively syphilitic in their origin. Assuming that these diseases may be due to other causes than syphilis, can any one draw a clinical picture of these diseases when caused and when not caused by syphilis? It seems to me that if no one can distinguish between specific and non-specific paresis or tabes, where the pathology is comparatively well defined, it is all the more impossible to define the part syphilis may play in the forms of mental malady where the pathogenesis is more obscure. Consider further, syphilitic hypochondriasis, so-called "syphiliophobia," and insanity occurring with the very onset of constitutional syphilis. In all such cases lowered brain nutrition, perhaps purely functional, is capable of accounting for the conditions, and it is not necessary to call in syphilis to explain them. High authorities affirm and deny that soft chancre or suppurating buboes are followed by constitutional syphilis. The views of Fournier—as good an authority as any—have changed from one extreme to another, and of late a new perplexity is introduced by affirming that hereditary syphilis plays an important part in the development of psychoses, especially in the adolescent period. Here again an obstacle to the full understanding of the case arises, because the proof of hereditary syphilis is not always convincing, since dementia, praecox, paranoia, and hebephrenia have not as yet been studied so that those of specific and non-specific origin can be differentiated, neither are writers agreed as to the adolescent form of paresis.

In a recent paper by A. W. Hurd[3] it is stated that syphilis may cause, 1, any simple psychosis; 2, paresis; 3, pseudo-paresis. By a simple psychosis I take it is meant one which has nothing characteristic of syphilis. Paresis is the same thing, whether caused by syphilis or not. Finally, in "pseudo-paresis" it is claimed to be characteristic to find a confused mental picture, as of paresis "toned down," or cerebral syphilis "heightened"; to find that motor disorders or cranial nerve symptoms precede; that hypochondria or acute delirium may appear early; that paralysis rather than ataxia plays the leading rôle; that mental dulness and a "vacant expression" are more noticeable, while we find that a gradual change in disposition, grandiose ideas and a sense of well-being are more marked in paresis. It is noted that motor symptoms, cranial nerve symptoms and ataxia are utilized to aid in diagnosis, but these I am not able to take into account in treating of purely mental phenomena, as my subject requires.

In a paper by J. H. McBride,[4] read in this Section one year ago, it is stated: "Syphilitic insanity may mimic every known form of mental derangement;" he also says that there is "nothing characteristic in the mania" or the depression due to syphilis, but that, if the entire history be considered, irregular features will be found; that in mania there will be the earlier appearance of confusion or weakness, with intervals of quiet

and semi-lucidity; in melancholia, brief depression, much confusion, outbursts of excitement, periods of stupor and early dementia. "These," he says, "may be regarded often as circumstantial evidence of a specific origin." The writer also mentions "loss of mental power, of self-control, of the self-regarding virtues, of moral sense, the detachment of life from the delusions," and many other morbid mental phenomena as "prominent characteristics." There is scarcely one of these phenomena or any combination of them which may not appear in an equally irregular manner in cases where there is no question of syphilis. A "confused mental picture," a "toning down" or "heightening" of various symptoms, an irregularity in the order they assume, predominance of paralysis or of ataxia or of cranial nerve symptoms, "hypochondria," "acute delirium," "vacant expression," etc., are symptoms that purely non-specific psychoses or those arising from alcoholism or non-specific arterial changes may present. So with the peculiarity of seeming to mimic other forms of insanity; and of irregular and atypical features or succession of symptoms.

The arguments in favor of syphilis from the "bizarre" and irregular character can have but small weight since "bizarrerie" is something we constantly see in cases where the question of syphilis is known not to enter, and certainly "loss of mental power" or of "moral sense" and of "the self-regarding virtues" have in them nothing that would aid in the diagnosis of a syphilitic psychosis.

If these two able observers find nothing in the mental phenomena more distinctive, one is inclined to think that it is because there is possibly nothing that is distinctive.

The tendency to "remissions" and to periods of return to apparent sanity does seem to mark syphilitic cases especially, though also known in those that are not syphilitic. In this matter again there is a difference of opinion as to whether the return to sanity is complete. Some writers, and among them Mott, claim that a certain dementia or weakening always remains; but I have known of cases where the return to normal condition was so complete that no expert could tell the difference, and such are reported by others. Mott explains these fluctuations by the fact that when the remissions occur, the disease is external to the nerve cell and functional in its nature.

It is doubtless true that the permanency of insanity and the failure to recover in simple acquired psychoses, may be due to the complication of syphilis, either hereditary or acquired. Some writers have given failure to recover as an indication or presumption of syphilis, but this fact itself helps not at all in the diagnosis of syphilis. Failure to recover is unhappily too frequent in all forms of insanity.

A correspondence may exist between the difference and variable nature of psychic symptoms and the irregularity of the pathologic changes of syphilis—so largely vascular in their origin. The irregular and temporary attacks of aphasia are somewhat characteristic, but are also found in other cases.

Some writers who claim lacunæ in the memory as characteristic, fail to note that lapses and gaps of memory are common in other forms, particularly alcoholic and epileptic forms, and yet these latter will be apt to be associated with acute attacks or other accompanying signs. It is perhaps questionable whether systematized delusions are ever found in syphilitic brain disease, unless there be a background of paranoia or degeneracy.

It is agreed that the anterior portions of the brain, frontal and central, are more open to syphilitic infection and this gives some characteristic significance to the frequent dulness and stupor. Again, the admitted correspondence between senility and syphilitic insanity speaks only for lack of characteristic features. Spitzka[5] gives the figures of Snell, who found that 75 per cent. of the cases of paretic dementia were due to syphilis; of Erb, who found a similar proportion of cases of tabes due to syphilis; of Mendel, who found 117 out of 291 such patients were syphilitic, while on the other hand Ripping found only 12 per cent. with a syphilitic history. Spitzka himself found syphilis in 33 per cent. of the pauper insane of New York. Clouston, in over 3000 cases, found but 16 of syphilitic insanity. Spitzka remarks that the attempt to test the question of syphilis by specific treatment fails, because in several cases spontaneous remissions occurred and in others the most energetic treatment gave no results. Then, too, specific treatment has been found useful where infection could be positively excluded. Finally, Ripping claims to have found syphilitic patients recover from insanity where no specific treatment was applied.

These statements, as well as innumerable others to be found in the literature, tend to throw doubt on claims that any given psychopathic condition is syphilitic, and yet as was remarked by Kraft-Ebing and agreed to by Mott: "The more we study paresis the more we find it associated with syphilis;" and the former declares with a measure of truth that civilization and "syphilization" go together, however discreditable this fact may be to the former.

The recent report of the Pathologic Laboratory of the London County Asylums by F. W. Mott[6] contains valuable information concerning the pathology of syphilis, the structural changes and to some extent the mental symptoms. That which seems most pertinent to the present inquiry in Mott's work is the placing in clearer light the fact that syphilitic brain disease, as distinguished from paresis, affects, primarily, vessels, lymphatics and membranes—mesoblastic structures—and the degeneration of neurons is secondary. Paresis, on the other hand, is a primary decay of the neuron itself, but it is not clear that the mental symptoms of the two processes can be differentiated. Indeed, Mott gives the phenomena of irritation and other psychic symptoms as characteristic of early changes in both. The primary progressive degeneration of neurons starts at the highest and latest developed structures, speech and association centers, and attacks by preference the frontal and central regions. Mott describes stupor, dementia, weakening or loss of memory and intellect, and many other symptoms, but does not give any distinctive characteristic of different syphilitic processes; neither can we distinguish these as being different according as syphilis is or is not found. Mott considers "stress" to be the important proximate factor in the development of brain disease, in one affected with syphilis. Stress is, however, perhaps equally the proximate cause in psychoses where syphilis is not concerned.

Since as yet we have in psychiatry so little in the nature of known definite psychopathic symptoms which can be associated with molecular or even coarse changes in the brain; since as yet we know nothing of the *modus operandi* of mental changes as associated with pathologic findings, and since our classifications of mental

5. E. C. Spitzka: Manual of Insanity, p. 244.

6. Annual report of the Pathologic Laboratory of the London County Asylums, 1900. Abstracted by J. H. McBride, Southern Cal. Pract., April, 1901.

disease are in a purely tentative and conjectural condition, it seems premature to attempt to formulate syphilitic psychoses. The very inconsistency and lack of type in symptoms taken by some to be indications of syphilis, are interpreted by Kraepelin to be characteristic of chronic and permanent mental deterioration—Verbloedung's processe. We all meet with cases for which there seems to be no place by any method of classification as yet devised.

Clinical psychiatry must unite psychical events in the course of each recognized psychosis, with a negative or positive report from the autopsy table, before the influence of syphilis on mental operations can be determined. We can not doubt but that psychic life is intimately associated with matter, i. e., with brain cells, but we are as yet without data which would enable us to connect objectively the functionating of those cells, either in health or disease, with any changes in their form or substance. Even the pathology of general paralysis, the best known of all, is only indefinite as to mental changes and their relation to physical changes.

I am aware that I have only touched the borders of this far-reaching subject, and that most of what I have written is only of negative value, if of any at all.

I have sought something more tangible in reviewing my records of the past six years, covering over 1200 cases of all forms of nervous and mental disease. I found among these 45 cases of well-substantiated, constitutional syphilis. Doubtless an equal or greater number which I rejected for want of definite knowledge might have been included without serious error, but considering only these 45 cases, they were made up as follows: 17 were diagnosed as paresis; 12 as syphilitic brain disease with symptoms of organic lesion; 7 were cases of psychoses with marked delusional characteristics and without symptoms of brain syphilis, the mental symptoms taking the form of delirium, stupor, extremes of exaltation and depression, aphasic attacks and mild dementia; 4 having ophthalmoplegia and optic neuritis: 4 were cases of hypochondriacal melancholia, and of these, 3 temporarily improved, the other was a morphin case: 2 were cases of tabes with emotional weakening as the only mental failure, and there was one case each of slight dementia, melancholia and dementia paralytica of senile form. The type of mental disorder in the 17 cases of paresis was expansive in all except 2; marked confusional condition was present in the two depressed cases, and in 9 of the expansive cases confusion was also a very prominent feature.

These cases were gone over and tabulated with reference to the following points: The type of hallucinations and delusions, where present; the cranial nerve symptoms; the evidence in each case of syphilis; the habits and occupation; the outcome as to the history of marked stress as a factor producing the mental disease, and the time of infection prior to appearance of psychopathic symptoms.

I found, however, that these tables possessed but little significance, partly because no useful deductions could be made from such small numbers, and partly because the exclusion of so large a number of probable cases for want of a positive diagnosis seemed to me in a measure to vitiate the result.

Progress in Peru.—The Lima medical papers are rejoicing over the accession of a portable disinfecting oven, and the bacteriologic laboratory recently installed in the public hospital, which, by the way, bears the unique name of the Second of May Hospital—"Dos de Mayo."

SYPHILIS OF THE NERVOUS SYSTEM—ITS GENERAL PATHOLOGY, WITH REMARKS ON TREATMENT.*

F. W. LANGDON, M.D.
CINCINNATI, OHIO.

The initial lesion of syphilis must be viewed, in the light of our present knowledge, as a wound plus infection, the infecting material being probably of bacterial origin.

The first nervous changes following such infection are localized at the sight of the initial lesion, and have been well described by Berkley.[1] Briefly, these changes consist of a combined interstitial and parenchymatous neuritis, due, in the investigator's opinion, to, 1, compression by the round-celled exudate; 2, endarteritis, interfering with nutrition; 3, local effect of a "virus."

The conditions found in the nerves are described as, 1, obliteration of lymph spaces; 2, disappearance of axons; 3, a "glassy" degenerated appearance of the myelin.

These changes were limited to the nerves imbedded in the round-celled exudate; those nerves not so surrounded being normal, or approximately so. Root-neuritis, cranial and spinal, and peripheral mono-neuritis may occur as secondary lesions.

Syphilitic multiple neuritis has also been reported, one case by Fry,[2] a year after the initial lesion; and a case by Cestan,[3] who notes three others with more or less doubt. The extreme rarity of the affection and the possibility of other causes in any given case tend to render the diagnosis problematic.

The second evidence we have of invasion of the nervous system by the disease or its products, is in the production of fever—"syphilitic fever"—often overlooked and sometimes misinterpreted.

The actual pathologic process at work here is unknown. Presumably, in the proliferation of the microbes of the disease, a toxin is set free in the tissues, which, carried by the blood stream to the cerebrospinal axis, irritates certain hypothetical thermo-genetic centers, or depresses certain other centers equally hypothetical, which are assumed to control or direct thermolysis. Another explanation to be considered leaves out of account any such "centers" and attributes the febrile process to alterations in the chemical constitution of the tissues generally, by the toxin of the disease. These alterations giving rise to perversions of metabolism with increased heat production or diminished heat dissipation.[4]

The third group of processes to be considered, that which is by far the most important to us, in a practical sense, is the inflammatory group whose characteristic lesion we call a "gumma."

The great fact of importance in this group, as regards nervous syphilis, is that gummatous syphilis in its beginning is a vascular syphilis.

Since all vascular organs are, in their developmental nature, of connective tissue (mesoblastic) type, it follows, as a corollary, that vascular syphilis is necessarily connective tissue syphilis. Hence to the tissues of this type (blood, dermis, basement membrane, areolar tissue, bone and cartilage), must we look for the initiation of the pathologic processes which invade the nervous, as well as the other anatomical systems.

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

Nervous tissue proper, therefore, owing to its non-vascularity, is never the primary seat of inflammatory processes, whether these be due to syphilis or to other causes.

While it may be said to be an accepted axiom therefore, that gummatous syphilis is primarily vascular syphilis, it does not follow that it must be an arteritis or a phlebitis. It is often a lymphangitis, using this term in its broad sense, to cover involvement of the lymph-channels generally of the nerve centers. Thus the so-called peri-arteritis is often a lymphangitis in its inception, beginning in the peri-arterial lymph sheath. There are reasons for the belief that gummatous meningitis of the diffuse form may be also of lymphangitic type. As regards the best known vascular lesion, arteritis, the discussion as to whether a "peri-arteritis" (Baumgarten), or an endarteritis (Heubner), is the more characteristic vascular lesion of syphilis, would seem to be a superfluous refinement in localization from either a diagnostic or a therapeutic view-point, since in either event the exudate is within the wall (not within the lumen) of the vessel, and eventually involves its entire thickness.

The important event in syphilitic arteritis is the impairment of the nutritional integrity of the endothelial lining, whereby thrombosis with its resulting necrotic softening is directly produced.

It is customary to picture the changes in the vessel wall as a heaping up of proliferated cells, presumably derived from the deep endothelial layers of the inner coat. It is not probable, however, that the closure of the vessel is ever due merely to mechanical effects of this accumulation. Long before closure would occur from this cause, the inner lining, which must be continually shed, molecule by molecule, has been replaced by the rapidly reproduced and hence imperfect cells of the deeper layers. These again are being gradually deprived of their nutrition—from the vasa vasorum via the intramural lymph spaces—by reason of the increasing pressure of the exudate in the middle and other layers of the vessel wall, and possibly in addition are directly affected by the toxin of the disease. Hence, it is only a question of time that the inner wall of the vessel at the affected area comes to be lined by an endothelium defective in nutrition, possibly actually necrotic in places. Thrombosis, then, is the inevitable result.

As regards the direct local cause of the endarteritis, we must assume that the active agents in its production, which are at present supposed to be bacteria, are carried to the points of inflammatory reaction by the vasa vasorum.

We reject the main blood stream (of the lumen) as a source of the infection of the wall, by reason of the fact that inflammation presupposes stasis followed by exudation. Stasis, however, is not likely to occur in a large or moderate-sized artery. It is only in the capillary plexuses of the vasa vasorum and their nutritive successors, the intramural lymph spaces; or again, in the terminal capillary plexuses of the ordinary artery, that conditions favorable to stasis occur.

Pathologically, therefore, syphilis of the central nervous system is primarily a lymphangitis, phlebitis or arteritis, or any combination of these. The product of the inflammation is an exudate consisting chiefly of small round cells with a tendency to, 1, central necrosis, when in massive collections—gummatous tumor—or, 2, a tendency to fibroid organization when spread out in thin layers—gummatous meningitis, diffuse arteritis, etc.

In accordance, therefore, with the stage and progress of the process we may have, 1, a gummatous thickening, plaque or tumor; 2, a caseous abscess; 3, a cicatrix. In either event the nervous manifestations are secondary and due to, 1, thrombotic occlusion of nutrient vessels causing necrotic softening in their areas of distribution; 2, mechanical pressure causing secondary degeneration of neurons or their processes; 3, interference with the return circulation in lymph channels, causing local toxic states; 4, arteriosclerosis of varying type, probably responsible for various nerve degenerations of chronic character, e. g., nuclear palsies, locomotor ataxia, paresis, etc.

The question naturally arises: Is all inflammatory syphilis essentially alike, i. e., due to gummatous deposits of varying shape, in and around arterial, venous or lymphatic channels? This must probably be answered in the affirmative; the differing "types" of gummatous disease, meningitis, massive gumma, and arteritis "obliterans" being variations due to differences in size, number and distribution of foci. The possibility of a "mixed" infection in some cases must be conceded; to this abscesses proper may be due at times.

Hereditary syphilis as it affects the nervous system, may develop as a gummatous arteritis or meningitis, pathologically identical with the acquired form in adults. Many of the infantile hemiplegias and spastic paraplegias are probably of this type. Defects of a developmental nature, however, also occur in children, showing themselves in the various forms of idiocy and imbecility, which probably rest in great part on a foundation of vascular degeneration. It is quite probable that the proportion of children showing distinct syphilitic lesions of hereditary origin is commonly overestimated, as compared with the non-syphilitic from the same class of parents. Almost every practitioner can recall numerous cases where the children of syphilitic parents have all escaped; and other cases where one child is marked with, and others free from, syphilis. Statistics bearing on this point would be desirable.

We must not lose sight of the fact that gross lesions, i. e., meningitis, gumma, arteritis followed by softening, are not the only results of syphilitic infection of the nerve centers. Encephalitis, in multiple and minute foci, situated about the terminal capillary plexuses of the cortex, may probably occur, damaging various association tracts and operating as an important factor in the production of syphilitic epilepsy, some of the psychoses, etc. Accurate observations on this form of encephalitis would be desirable.

What is the most frequent site of the gummatous process in the nerve centers? This question is evidently a difficult one to answer, since many cases present multiple lesions. Most authors state that, 1, basilar meningitis is the most frequent cerebral lesion. Next follow in order, 2, meningo-encephalitis of the convexity; 3, arteritis with thrombosis and softening. In the cord, the most frequent lesion is said to be a meningo-myelitis; next to that arteritis with local softening. The writer's experience is at variance with this statement as shown by the following analysis: In 100 consecutive cases, about equally distributed between hospital and private practice, the preponderating lesion was diagnosed as follows:

Thrombosis with softening (hemiplegia)	41
Meningo-encephalitis of vertex	23

Basal meningitis	11
Cerebrospinal disseminated lesions	10
Focal myelitis (including also "transverse")	12
Meningo-myelitis	3

Excluded from the enumeration, but in serial connection with it are:

Massive gumma	1
Psychoses (probably of meningitic or encephalitic origin)	2

Another question of importance is: Has chronic diffuse syphilitic arteritis any distinguishing features by which it may be recognized from arteriosclerosis due to other causes (chronic uremia, gout, alcohol, etc.)? To this most competent observers reply in the negative.

It has been assumed[5] that, in the localized softening following a syphilitic thrombosis, we have an "ordinary" or non-specific lesion to combat. Is this true? Probably it is, for a short time, of the softened area itself. But what follows this softening? In the surrounding tissue, hyperemia, exudation, proliferation; in short, secondary inflammation. Is this non-specific? It would be remarkable to think it was when we reflect upon the proximity of the original infected vessel. We all know the tendency of ordinary external wounds in a syphilitic to take on the "specific" inflammation; and how often they heal slowly or refuse to heal, until treated with anti-syphilitic remedies.

NATURAL HISTORY OF SYPHILIS.

During the early or "primary" period of the disease, following immediately upon the infection, we must assume the local proliferation of the microbes (bacteria?) and the collateral production of a toxin which produces a localized degenerative neuritis as well as the "general" symptoms, fever, malaise, muscular pains, etc. This period probably terminates, as does the febrile stage of the ordinary exanthemata, by reason of the production of an antitoxin which terminates the life or activity of the micro-organisms in great part, leaving, however, a few, possibly in a "sporule" stage for the future development of foci of gummatous inflammation in various situations. This is probably the natural course of the disease when uninfluenced by treatment of any kind.

The writer has seen such a case, untreated for thirty years, in a man of 55, who had received internal medicine (nature unknown) for only a couple of weeks at the time of the initial lesion. All these years he had been subject to repeated crops of subcutaneous and intramuscular gummata which had caseated and cicatrized, with little or no interference with his general health, and which he ascribed to hereditary "scrofula" in his system, of which there was, in my opinion, no evidence. When he consulted me for a paraphasia verbalis without paralysis due to slight thrombotic softening, he had two of these caseating gummata on the back, each as large as a pigeon's egg, of which he made no mention, so accustomed had he been to the presence of similar lesions for thirty years. On stripping him for examination these were discovered, and in addition, dozens of characteristic cicatrices, and intra-muscular indurations, situated on trunk and extremities, marking the sites of former gummata. He made a fair recovery from the aphasic symptoms and was kept upon mercury and iodids at intervals for about two years, during which time he enjoyed fair health. He had all his life an especial liking and capacity for mathematics, and this was apparently not diminished. As he lived at a distance he became somewhat irregular in his visits and when he consulted me again, after an absence of some months, he presented a marked motor aphasia, with slight right hemiplegia and a mild degree of dementia, probably all due to multiple foci of softening. Death followed in a few months.

The gummatous process is, therefore, in a measure self-limited. It is also in its inception to be viewed as a conservative process; like all inflammation it is evidence of resistance to an invader. When this disappears the gummatous process, like other inflammatory actions, ceases. What checks it? Three things:

1. The insufficient blood supply at its center, leading to necrotic softening and caseation.

2. The possible (even probable) development of an antitoxin which checks the local proliferation of microbes.

3. Removal of the necrotic tissue in part, by the leucocytes of the surrounding exudate, or, in the nerve centers, possibly by the mossy glia cells (scavenger cells of Bevan Lewis).

4. Organization into cicatricial tissue of the remaining elements of the inflammatory exudate.

Pathology is certainly of greatest value when it points the way to a rational therapy. May we hasten in any manner the more desirable of these processes? This, it seems to me, is the therapeutic problem to be solved.

While the limits assigned to the present paper forbid any extended or detailed remarks on treatment, some general considerations of the subject may be permissible.

We have come to speak so confidently of treatment by mercurials and iodids as "specific" treatment, that it does some violence to our therapeutic optimism to question their "specific" attribute. And yet it seems that we must logically admit this to be a fragile idol, likely to be shattered by the cold logic of the laboratory. Do these remedies destroy the germs of the disease? Few will claim this at the present day. The hypothesis of Gowers and others, that they may destroy the germs but not the "spores," is an attempt to explain the obtrusive fact that they do not, as a rule, prevent future gummatous developments. How then may mercurials and iodids act in gummatous disease? They are erroneously called 'absorbents," but we know that no drug is an absorbent. The very term absorbent, as applied to drugs, is almost as objectionable as that other absurdity, "keeping the bowels in a soluble condition."

What useful purposes may these remedies subserve in promoting the disappearance of syphilitic exudates? Simply and solely to destroy the already feeble vitality in the newly developed cells of the gumma, to poison them in fact, after which fatty degeneration, necrosis and liquefaction naturally follow. The lymph spaces, the real absorbents, do the rest. Thus the available material for future cicatricial tissue is reduced to a minimum, with corresponding lessening of future pressure and nerve degeneration.

How may these remedies act in the florid stage of the disease? Simply in the same way, so far as we know, namely, by promoting disappearance of inflammatory accumulations. Few will claim that they actually destroy the germs.

It is conceivable, however, that by stimulating excretion generally by the bowels, kidneys, and skin, they may also promote elimination of a considerable portion of the toxin proper. We should not lose sight of the fact, moreover, that these agents used within proper

limits may stimulate the activity of the hemopoetic system, producing a degree of leucocytosis which may be useful in combating the microbes proper. Thus are we relieved of any necessity for a therapeutic nihilism.

In some cases the natural vigor of the patient, assisted by remedies judiciously used and hygienic measures, may apparently exhaust the stock of microbes and the patient remain well of active syphilis at least.

Does this render him secure from degenerative changes? Statistics appear to show that it does not—(Collins[10]). What then may be the cause of such degenerative diseases as locomotor ataxia, paresis, etc.? The hypothesis most in favor at the present day, is that of Strümpell that it is a post-syphilitic toxin, a by-product, so to speak, of the vanished syphilis, which, circulating in the blood, poisons the neuron, but does not excite inflammation. This hypothesis is untenable in the cases, well attested, of locomotor ataxia and paresis, without preceding syphilis. A more plausible explanation, to the present writer at least, lies in the fact of extensive fibroid and hyaline vascular changes, which affect the arteries both in syphilitic and non-syphilitic subjects. (*Vide* Berkley.[7]) The syphilitic toxin, while it must be conceded a frequent cause, is certainly not the only cause of vascular degeneration.

A long-standing and widespread arteriosclerosis or hyaline degeneration is a sufficient factor for the production of degenerative nervous disease, without the intervention, at the time, of any toxin. Thus we may account for many cases of degenerative nervous disease without necessarily invoking the aid of a post-syphilitic toxin, or of syphilis in any form.

Are mercurials and iodids of value in these degenerative nervous diseases? Modern neurological opinion tends to the view that they are not. From what has been said of the modus operandi of these remedies, it is difficult to ascribe to them any virtue in non-inflammatory nervous lesions, where the neurons are undergoing a molecular death from starvation. What good effects are observed from them are in all probability due to collateral influences on secretion and excretion, apart from the nervous degeneration proper.

As collateral at least to the present topic, we may ask, should we withhold mercurials and iodids in a central softening from non-syphilitic thrombosis or hemorrhage? I think not. The fact that these remedies are obnoxious to all newly formed tissue elements, may render them useful in the secondary exudation which always surrounds a gross vascular lesion in the nerve centers. Hence, judiciously used they may limit the amount of organizable material and thus lessen the consequent area of irritation or degeneration in adjoining nerve elements.

It sometimes happens that a patient with extensive cerebral softening, under mercurial treatment, develops a marked rise of temperature. This is not necessarily or even probably mercurial fever in most cases. It would appear to the writer to be due to the rapid breaking down of the necrotic area and the cellular exudate, with the absorption of the debris into the general circulation too rapidly to admit of complete oxidation and excretion. Hence, the pyrexia is more or less septic in origin. It is wise in these cases to omit mercury for a few days and then resume it when the fever subsides.

May vascular disease, widely spread, without foci of gummatous growth, exist as a result of syphilis and give rise to marked nervous manifestations?

The probability is that it may. Berkley[6] has reported two such cases; one with autopsy, in which the chief vascular findings were an extensive and widespread infiltration of the media of the arteries with a hyaline-fibrous material which materially narrowed and in some places even occluded the caliber.

This degenerative change was present in the arteries of the gray matter of the cord, more particularly in those of "Clarke's columns," and in the medulla oblongata; it was also present in the spinal root arteries and in the skin tissues. The writer has under observation a case presenting similar clinical features, in which, however, syphilis can not be traced.

The importance of recognition of this condition when possible lies in the fact that no therapeutic measure known to us has any favorable influence on hyaline vascular degeneration. We may do well to remember, however, that combination of degenerative lesions and inflammation are frequent (Berkley[7]) and that remedies may exert a favorable influence on the inflammatory element.

One more reference to therapy in the light of modern pathology. What have we to look forward to as an improvement upon present modes of treatment? The discovery of an antitoxin serum treatment, similar to that of diphtheria, must be conceded as possible. The arrest, and caseation or cicatrization of gummatous exudates in cases untreated by medicines, as in the one before cited, furnishes us a basis for hope in this direction. The difficulty of transmitting syphilis to the lower animals, which has heretofore hindered experimentation in this direction, will not necessarily always remain unsurmountable.

Neviorovsky[8] has reported favorable results in recent syphilis, from injections of human serum taken from subjects of tertiary syphilis.

Again, remarkable results in two cases have attended the use of Hayem's artificial serum (sodium chlorid 7 gm., crystallized disodic phosphate 2 gm., water 1000 gm.). Half of this was injected every five or six days in addition to mercury and iodids, in cases, which had obstinately resisted the latter remedies alone. The lesions yielded rapidly to the combined treatment.[9]

SUMMARY.

The pathological processes concerned in syphilis of the nervous system comprise:

1. A localized parenchymatous and interstitial neuritis at the site of the initial lesion, due to endarteritis, compression and local toxic action.

2. A localized root neuritis (cranial or spinal), and a peripheral mono-neuritis, both of gummatous type, may occur in the "secondary" stage. A generalized or "multiple" neuritis has been reported, but is so rare as to be a pathological curiosity and open to doubt as to origin.

3. A generalized toxemia affecting the nerve centers directly or metabolism in general and producing febrile reaction of a "specific" type, i. e., "secondary" fever.

4. Inflammatory ("gummatous") lesions, due to disseminated or localized vascular infections. The arterial walls are the chief seat of these gummatous exudations, and the exudate may begin as a "periarteritis," a mesarteritis or an endarteritis, eventually in most cases becoming a "panarteritis"—Berkley. The exudate is always intra-mural—not intra-lumenal—the narrowing of the lumen being due to concentric or nodular thickening of the walls, and heaping up (proliferation) of the deep endothelial layers of the intima. Necrotic changes in the inner layer probably precede thrombosis.

The infecting material (bacteria?) probably reaches the vessel wall via the vasavasorum, from which a portion of the exudate at least is derived. Direct infection of the lining endothelium, by the main blood stream, is unknown and probably does not occur, excepting in the terminal capillary plexuses.

The materials constituting the inflammatory exudate in all forms of gummatous syphilis, whether arteritis, meningitis or tumor are biologically identical, the differences which exist anatomically being due to location and distribution of the exudate. The characteristics of gummatous syphilis of the nervous system are: (*a*), the lesions are primarily vascular; (*b*), the lesions are usually multiple; (*c*), the lesions are usually non-systematized in a neurological sense, though they show a predilection for certain localities—namely, the basal meninges, and the arteries of the basal ganglia and motor area; in the cord, the meninges and the ventral horns.

5. Gummatous lesions are, in a measure, self-limited, their growth being checked by: (*a*), central necrosis, due to deficient vascularity; (*b*), the probable development of an antitoxin which checks the local proliferation of microbes; (*c*), fatty degeneration and absorption of the fluid portions with caseation or cicatrization of the remainder.

6. Degenerative nervous processes, due directly to syphilitic exudations, are of two types: (*a*), "compression" degeneration due to prolonged pressure by gummatous masses or their cicatricial sequelæ which separates various neuron processes from the influence of corresponding "trophic centers" (neuron bodies); (*b*) secondary degeneration consequent upon destruction of these same neuron bodies by softening, of thrombotic or hemorrhagic origin. The preceding two types are classed as "non-systematized" degenerations, in contradistinction to:

7. Degenerative diseases, of "systematized" type, such as locomotor ataxia and paresis. These should probably be looked upon as malnutritional affections due in part to arterial degeneration (fibrous or hyaline or both) which may or may not be of syphilitic origin; and in part to inherent individual predisposition to early dissolution of certain physiological systems. These degenerations are not benefited and may be made worse by vigorous anti-syphilitic medication.

8. Remedies of value in syphilis may act in three ways: (*a*), the most usual, by promoting necrosis in the embryonic cells of the exudate, thus permitting their removal in large part by the lymph channels; (*b*), by stimulating the excretory organs generally, thus favoring removal of "toxins" produced by the disease; (*c*), possibly by the promotion of leucocytosis and other tissue changes, which set free an increase of the natural amount of (hypothetical) antitoxin. In no case do these remedies act as "absorbents" or "stimulate the absorbents," nor have we reason to believe that they destroy the microbes of the disease.

9. Any lesion of the nerve centers, attended or followed by inflammatory exudate, whether syphilitic or non-syphilitic, may be favorably influenced by the judicious administration of mercurials and iodids; and subsequent amount of damage by cicatricial compression or irritation be materially lessened.

10. The discovery of a means of producing artificially an antitoxin which shall arrest the disease in an early stage, must be conceded as a possibility.

DISCUSSION ON SYMPOSIUM ON SYPHILIS OF THE BRAIN.

Dr. C. B. Burr, Flint, Mich.—The fact which Dr. Patrick alluded to, in connection with the case mentioned, namely, that the history of infection so many years before caused him to doubt whether syphilis was at the bottom of the symptoms presented, would have led me to the opposite conclusion, inasmuch as in my experience ten or fifteen or more years may elapse after infection before the development of cerebral syphilis. My practice, however, is largely among patients presenting mental disturbance with brain syphilis.

Of cerebral syphilis accompanied by marked disturbances of the mental operations there are two interesting varieties: one in which motor symptoms predominate; the other in which the symptoms are altogether psychical. They are both characterized by reduction. This is their most conspicuous quality. In the one the symptoms are clinically difficult to distinguish from those of paretic dementia. However, there is less apt to be expansive delusions, remissions are more frequent and the disease is of longer duration. In the second variety there is psychical reduction, manifested in dementia, the symptom of lack of memory being the most prominent. There is also hebetude and the patient is dull and unresponsive.

Dr. H. D. Valin, St. Peter, Minn.—I would like to say something about the bacteriology of syphilis. About 1896 an investigator in Baden, Germany, thought he had discovered the bacillus, and he published a pamphlet on the subject. An insane asylum is not a very good place in which to study the bacteriology of syphilis, as in my experience, cases of recent syphilis are rarely encountered there, but I thought I could get some outside cases, and through the courtesy of our late commissioner of lunacy I secured some pus which he assured me came from a syphilitic bubo. This remained for two or three weeks without undergoing any putrefactive changes, which agrees with the statement that has been made that syphilitic pus contains some element which retards putrefaction. Upon examining this pus, I found a small bacillus, staining by Gram's method, which had the characteristics of the bacillus that has been described by Van Niessen. After the pus had been kept for several weeks, increased numbers of this bacillus were found. With this pus I also undertook some inoculation experiments upon animals, and in one of the animals I found three growths in the liver which had the gross appearance of gumma and appeared so upon section.

In another case I was called upon to make a blood analysis by a surgeon not far from St. Peter. This patient had been operated on by another surgeon, who saved the man's life, but the operation left a biliary fistula. In the blood and bile of that patient I found a few small bacilli which were similar to those described by Van Niessen. I found it very difficult to cultivate these bacilli. The work must be done on gelatin. The characteristic changes observed in the gelatin are these: After seven or eight days the upper layer will begin to liquefy, and this will continue until the gelatin is completely liquefied, and at the bottom is a mass of detritus which on staining shows the bacillus. This process of liquefaction also takes place when streptococci are present. Van Niessen states that he found the bacillus even in chronic cases of syphilis of the

florid type. In a case of syphilis which came under my observation an examination failed to show any of these bacilli.

DR. E. G. CARPENTER, Columbus, Ohio—There are two points that I have observed in syphilis of the cord and brain. In the first place, in syphilis of the cord, and particularly in those cases where the disease has involved both the brain and the cord, I have noticed atypical reflexes, that is, they were active on one side and absent on the other, with more or less spasticity accompanied by ankle clonus. Another symptom which I have observed, is a slight loss of memory and some degree of dementia, with an accompanying depression sometimes amounting to melancholia. This, in my experience, is rather a common symptom in these cases, and it is in keeping with what we find in other diseases resulting from infection. For example, I have noticed this same symptom of depression in la grippe and typhoid fever.

DR. JOHN PUNTON, Kansas City—If the postulate laid down by Dr. Patrick in his paper is true, namely, that the symptoms in connection with cerebral syphilis are apt to present themselves within the first year and gradually decrease in frequency and severity as time goes on, then we must revolutionize our teachings in regard to the symptomatology of cerebral syphilis. From what the Doctor says, however, it would seem that he bases his claims on clinical knowledge. There are one or two points in connection with this subject that have not received sufficient emphasis. One is the temporary remission of symptoms that is not infrequently observed in cerebral syphilis. The patient may apparently be seriously ill on one day, and markedly improved the next.

DR. EDWARD E. MAYER, Pittsburg—The postulates set forth by Dr. Patrick may perhaps be a trifle too emphatic, and yet they certainly have a good deal of truth in them. Certainly, his statement regarding the onset of cerebral syphilis and the presence of the initial symptoms agrees with what I tried to say yesterday in the discussion of Dr. Norbury's paper upon paretic dementia. Because syphilis has occurred ten or twenty years before, we should not ascribe to it the cause of the dementia, and the same is true here. In the symposium on syphilis of the brain to which we have listened, the essayists very rightly separated the somatic from the psychical conditions. One symptom to which I desire to call attention is the partial psychic defect. Dr. Patrick ably presented the characteristic features—the bizarre coming and going of symptoms, the progressive dementia; the coma, and the remissions and exacerbations which are so characteristic of brain syphilis.

DR. SYDNEY KUH, Chicago—If there is one thing that is peculiar to the syphilitic psychoses, it is the intermittent and irregular character of the symptoms. One of these intermittent symptoms is perhaps especially characteristic, although it was described nearly fifty years ago; it is almost forgotten to-day. I refer to the symptom which went under the name of the intermittent aphasia of Mauriac. As far as I know, the character of this intermittent aphasia is almost invariably motor. The first attack, which is incomplete and temporary, is followed by a second and more severe attack and the condition finally becomes permanent. Often it is the only symptom. I do not think such a recurrent motor aphasia occurs in any disease excepting in syphilis of nervous system and paralytic dementia.

Perhaps the importance of nocturnal headaches as a symptom of cerebral syphilis is somewhat overestimated. My experience in the last few years has brought under my observation several cases with distinct and severe nocturnal headaches which I had good reason to believe were not of syphilitic origin. In one, the postmortem showed an immense abscess of the lobes of the brain. Very little has been said about the treatment of syphilis, and perhaps it might not be amiss to call attention to one method which in very severe cases has given me most satisfactory results. I refer to the intra-venous injection of corrosive sublimate, as recommended by an Italian writer. The method seems more dangerous than it really is. A local thrombosis may follow the injection, and occasionally there is ulceration; this has occurred in two out of the twelve cases where I have resorted to this method.

DR. FRANK P. NORBURY, Jacksonville, Ill.—Dr. Langdon, in his paper, spoke of the fever in syphilis. Some few years ago I observed a case of cerebral syphilis, or rather a case of acute insanity, the victim of syphilis in its secondary stage. During the first six weeks of the patient's stay in the hospital, I noticed a daily elevation of temperature. Whether this was due primarily to the syphilis or not I do not know, but I am inclined to believe that it was, and that the action of syphilitic poison in this case was the direct cause of the acute insanity. Melancholia was the form of mental disease, and I took it that the toxemia was so profound as to disturb nutrition, just as is noticed in typhoid fever, rheumatism and other infectious fevers. He recovered from his insanity and went to Iowa, where he subsequently resided. One day, eighteen months after leaving the hospital, he fell while walking along the street, and was picked up unconscious. He died in the course of a few days, and his death was attributed to some acute brain trouble.

DR. DEWEY, in reply—I do not know that I have anything more to say, unless it may be to give the periods of time that elapsed in my cases between the syphilitic infection and the onset of the insanity. In one case the insanity followed the infection within two years; in two, within three years; in three, within six years; in four, within seven years; in three, within eight years; in two, within nine years; in one, within ten years; in one, within twelve years; in four, within fifteen years, and in one, within sixteen years. In one, where nineteen years had elapsed since the syphilitic infection, the possibility of a second infection was thought of. This was the case of a religious brother who had been engaged in his priestly work for twenty years. He frankly acknowledged that he had been infected previous to that time, but the circumstances were such that a second infection could scarcely have occurred.

The symptom of loss of memory, to which one of the speakers referred, can not always be regarded as diagnostic of cerebral syphilis. It may be due to other causes. With reference to the intra-muscular use of bichlorid solution, I had a patient upon whom this method of treatment was employed. He thought the hypodermic injection was given to him for sedative purposes, and regularly fell asleep soon after administration.

DR. LANGDON, in reply—The suggestions made by Dr. Kuh were referred to in that portion of my paper which I did not get an opportunity to read. I mentioned the fact there that in the treatment of syphilis several improvements upon our present methods have been suggested by various writers. Among these is a Russian who in two or three very obstinate cases has employed an antitoxin with very favorable results. The antitoxin is obtained from the serum of old syphilitic patients, and is given by hypodermic injection.

PREVENTABLE DISEASE IN THE ARMY OF THE UNITED STATES—CAUSE, EFFECT AND REMEDY.*

MAJOR W. O. OWEN, M.D.
FORT THOMAS, KY.

Owing to the fact that my ideas, as expressed in a pamphlet that I had printed for private circulation, have appeared in part in the public press; and fearing that some one may be misled as to my intention and thought, I have concluded that it were better to express myself as fully as I can to the Academy of Medicine of Cincinnati and through it to the profession at large. I had no thought of making an attack upon any individual and therefore carefully abstained from using the name of any officer where possible offense might be taken. My aim was to call the attention of my professional brothers to a state of affairs which appeared to me was costing the Government large sums of money and the soldier great and unnecessary suffering from preventable disease, to call attention to the fact that the Red Cross of the Geneva Convention, which was intended to protect the surgeon, was actually a menace to his personal safety, for he was unwittingly using it

* Read before the Cincinnati Academy of Medicine, Oct. 7. For discussion, see p. 1130.

to protect property which belonged to the fighting force and was only loaned to the hospitals for temporary use. To ask you if you felt that you could agree with the position which I have taken that you put your shoulder to the wheel and help me to see if we could not as a body be able to create a public sentiment which in the future would lead to the correction of this, which I believe to be a wrong inflicted on the soldiers of all armies. I have seen in print that many medical men were sacrificed to save the military officer in the Crimea from the public clamor. Has not similar matter happened in the United States?

There occurred from May, 1898, to June, 1899, in the armies of the United States, deaths from: diarrhea and dysentery, 342; typhoid fever, 2774; homicide, suicide, and gunshot wounds, 1020. Out of a total death of 6619: diarrhea, dysentery, and typhoid fever, 3116; homicide, suicide, and gunshot wounds, 1020. This is slightly more than three deaths from these well-known preventable diseases to one of homicide, suicide, and gunshot wounds. (See Table VII, page 349, Report of the Surgeon-General United States Army to the Secretary of War, 1899). It will be noticed that this includes the battle casualties of Cuba, Porto Rico and the Philippines to June, 1899. Was this loss an imperative military necessity?

I believe that the day has come when all sanitary matters of the army should be placed under the control of the Army Medical Department for the reasons:

1. That by so doing very large economies may be made in the maintenance of the army, both in money to the United States and in suffering to the individual soldier.

2. To enable the Army Medical Department to obtain the immunity guaranteed by international treaty, which at present is not fully done.

Under the first head I would call attention to the fact that nowhere in statute law are the duties of the army medical man laid down except in one place, which says that he shall attend to the families of officers and men free; and in one other, that the Secretary of War may assign him to such duties as he may deem for the best interests of the service: *"Provided,* that the medical officers of the army and contract surgeons shall, whenever practicable, attend the families of officers and soldiers free of charge." (Supplement Revised Statutes United States, Chapter 217, Paragraph 6, Vol. I, p. 457.) "That medical officers of the army may be assigned by the Secretary of War to such duties as the interests of the service may demand." (Supplement Revised Statutes United States, Vol. II, Chapter 270, Section 3, p. 53.) The opinion expressed by a medical officer that a man has defects that disqualify him for service as a soldier is not final; it is a common thing for these men to be accepted by special authority, the defects being noted on the enlistment papers.

There is no regulation, so far as I know, and I think that I know, which requires an officer in charge of construction to submit the plans of construction to the Medical Department for an expression of an opinion as to the sanitary results before beginning the construction. The result is that every post at which I have served, even the most modern, is full of sanitary error that has cost much money to correct, when it has been corrected. Much disease has been the result.

In the annual reports of the Surgeon-General will be found each year accounts of many faults of sanitation which have been reported in the preceding twelve months. Each of these faults could have been prevented by proper medical advice at the time when the original construction was being made. When examining these reports it should be borne in mind that attention is only called to the more glaring instances which have been brought before the office and that the mass is too great to be placed in an annual report.

All that the Medical Department can do is for its individual members to report errors and recommend their correction. It is only a courtesy when the commanding officer listens to his medical officer. He is compelled by regulation to listen, but he is given the expressed right not to carry out the recommendation made by his medical officer for the prevention of disease amongst his men. In other words, he is given, by regulation, control over matter of which he has no adequate knowledge, as witness the following:

1392. The Medical Department, under the direction of the Secretary of War, is charged with the duty of investigating the sanitary condition of the army and making recommendations in reference thereto, with the duty of caring for the sick and wounded, making physical examination of officers and enlisted men, and furnishing all medical and hospital supplies, except for public animals.

1393. The surgeon, under the direction of the commanding officer, will supervise the hygiene of the post or command, and recommend such measures as he may deem necessary to prevent or diminish disease. He will examine, at least once a month, and note in the medical history of the post the sanitary condition of all public buildings, the drainage, the sewerage, amount and quality of the water supply, the clothing and habits of the men, and character and cooking of the food, and immediately after such examination will report thereon in writing to the commanding officer, with such recommendations as he may deem proper. The commanding officer will return the report, with his views and action indorsed thereon, and if he deem the action recommended impracticable or undesirable, will state fully his objections. The indorsement will be recorded in the medical history of the post, and the report and indorsement will be forwarded by the surgeon, through military channels, to the Surgeon-General. (Army Regulations, 1895, 1392-93.)

Constant changes are being made in posts by the quartermaster affecting sanitation. The surgeon, supposedly in charge of sanitation, finds or may not find them out before some one is dangerously ill or dead. If not before the disease has arisen, a search is then made, and reveals new and dangerous changes made in work previously inspected and found to be in good shape. Should he ask about it, he will be informed that these changes were made by the quartermaster whose business it is to look after construction.

At Fort ———— each company has ten wash basins, arranged in two gangs of five each, one gang on each side of the common trap and vent. This is a violation of the rules for plumbing issued from the Quartermaster's Department in Washington, D. C. It is also a violation of the plumbing rules of all of the large cities.

In time of war military necessity must control, but every precaution both in peace and war, but particularly in war, should be taken to put the soldier upon the highest plane of physical and mental excellence, so that he may be able to reach the highest efficiency as a fighting machine. Yet I have seen men drilled morning after morning in dew-laden grass until they were wet to the knee; have seen them living in overcrowded barracks, making a large sick report without actual necessity, etc., and the medical officer powerless to do aught but recommend.

Take the report of Lieut.-Col. A. S. Kimball, Quartermaster's Department, on the water supply of the Presidio, Cal. (See Report Surgeon-General United States Army to the Secretary of War, 1896, pp. 137-38). His report shows a water of undoubted high quality. He has based his report on the analysis made by Thomas Price & Son.

It is evident that these chemists were not informed as to the character of the water-shed from which this water is obtained. Mountain Lake, from borings around which this water is obtained, has a water-shed of two and one-half to three square miles; it is composed of seashore sand resting on a bed of rock. In this water-shed are three of the largest cemeteries of the city of San Francisco. A very large part of this water-shed is a closely-built city, with sewered streets, which sewers have uncemented brick bottoms. There are many animals stabled in it; all of the fecal matters of these animals and of this population is stored in this water-shed; all of the products of the decomposition of the bodies buried in these three graveyards drain into it; all of the excrement and kitchen waste of old Camp Merritt were buried in it. (There were some 18,000 men camped in this camp.) So long as the sand retains its ability to filter properly the water will be safe; when it becomes saturated with filth the health of the soldier at the Presidio will suffer. The water level of this lake has been lowered some twenty feet since the pumps have been at work. The officers of the Marine-Hospital Service tell me that they are afraid to use this lake water without first subjecting it to sixty pounds of steam. I made a careful chemical analysis of this water in 1899, and a careful personal inspection of this water-shed; it was self-evident that there must be contamination from animal source.

I believe that the analysis of Price & Son was correct when made; that the differences that exist between us are due to changes which have taken place from the increased number of bodies in the water-shed, from the increase in the population within the water-shed; that with these two causes that the sand is more soiled, and therefore no longer filters so well as formerly. It is a well-known fact that when sand is well aërated and not overloaded that it will filter out from 98 to 99.5 per cent. of all the germinal matter present.

Point Lobos Creek is the natural drainage channel of this water-shed. I was informed in the office of the Spring Valley Water Company that it had been formerly in use as a water supply for the city of San Francisco but that it had been abandoned for such use as it was too polluted.

The Presidio, with a water supply from this water-shed, was especially chosen as a model camp in which to assemble the troops for Philippine service, and the muster out of the returning volunteers.

Gen. ————, in his testimony before the war investigating commission, says in effect that he did not listen to his chief surgeon as to the medical needs of those commands that were to be detached from him; that he took from others and gave to his personal corps medical material on requisition that his chief surgeon had disapproved; that he compelled his chief surgeon to personally look after a division hospital instead of allowing him to look after the larger duties of his position; that he himself, in his own person, set the example of defying the recommendation of his Medical Department in drinking from a well that he was informed that the Medical Department had said was unsafe to use, and that he permitted the broken pump to be repaired so that the well might still be used. (See pp. 3080-81-85-86, Commission's Report, War with Spain.)

The general in a letter dated Nov. 12, 1898, uses the following language concerning his chief surgeon: "In the matter of the location of the troops in the camp, Col. ———— was not consulted, so far as my recollection goes, nor did I deem it necessary to consult him; there was no need of it. Any 'protest' he made received such attention as the importance of it required."

The report of Reed, Vaughn, and Shakespeare says:

> Some regiments at ————, as we have shown, were so located that they received the drainage of other regimental camps. There was certainly no sufficient excuse for this. . . The —th Indiana was forced to contract its lines to half the regulation distance, and it was then only 30 feet distant from the —th Ohio. The sinks of the last-mentioned regiment and the kitchens of the —st West Virginia were only 12 or 15 feet apart." . . . (The —th Penn.). This command reached —— May 20, and was unfortunately located on low ground. Requests for a change of location were repeatedly made in June and July. The soil became muddy; the camp received the washings from the other camps above; the sinks rapidly filled with water and overflowed, and still requests for a change in location were unheeded until August 12.
>
> As we have already seen, some regiments were improperly located from a sanitary standpoint. This was done by superior line officers, and sometimes in the face of protests from the medical officers. We have also seen that requests for a change in location were disregarded and regiments were allowed to occupy one site for too long a time. In general the camps became very filthy. It must be therefore admitted, it appears to us, that line officers were to some extent responsible for the conditions of the camps under their command. The medical officer can only recommend; the line officer can command.

Again the letter of the general continues: "Col. ————'s impression of the water was not borne out by the analysis of it." Of this command 21.56 per cent. suffered with typhoid fever, and 714 men died of this disease in this camp.

What opportunity have sanitary officers to have their recommendations carried out; what opportunity to prevent disease, when the general in command treats his chief surgeon with disrespect both as to his person and as to his recommendation; when the general himself drinks a water that he is informed has been condemned by the sanitary officer? In another place, when the general has read to him a report made by a sanitary officer concerning this camp, he requested that he might be given a copy of the report, so that he might bring the reporter to trial before a general court martial. He was informed that it was not protected testimony, and where a copy could be had. His further action is not known.

The mortality of the Spanish-American war was 28 per 1000 living. The mortality of men in civil life, including the lame, halt, and the blind, is about 8 per 1000 living between 20 and 35, the age limit of the armies of the United States. The enlisted soldier of the army of the United States is selected carefully from the flower of young American manhood. Young men physically sound between 20 and 35, with proper sanitary care, should not have a mortality of more than 1 or 2 per 1000 per annum; excess over this means careless sanitary work, and 28 per 1000, which was the average of the Spanish-American war, means that the work was badly done in these camps, and that more than four-fifths of these diseases and deaths should have been prevented; they were not a military necessity, for no enemy was near. These lives should not have been

taken; their mothers, wives and sisters should not have been thus grieved; the Government should have been spared this loss of life, and the loss of money needed to replace the dead and disabled, to pension the widows and dependents of the dead and to pension the disabled.

So far there has been allowed 6000 pension claims for the Spanish-American war; 44,000 claims are still to be adjusted. One to seven so far has been the average allowed; if these receive $100 per annum (the average for June, 1900, was $169.10) and the ratio holds, it means that the annual pensions for this war at present amount to $1,200,000, or the interest at 3 per cent. on $40,000,000.

Fully two-thirds of this list should have been saved by avoiding pensions to men disabled by preventable disease. These men are now disabled or dead; they, their widows and dependents, are to be cared for by the Government. How much better to have so cared for them that they had been returned to the bread-winners of the country! The normal death-rate of times of peace is largely increased in war times, not from injury, as many suppose, but from disease. These diseases are not so much from marching and maneuvering for battle position, but to the insanitary conditions of the camps, which, under a proper responsibility before the law of the land, can be easily corrected.

Look at the testimony given before the commission to investigate the Spanish-American war concerning Camp Alger, Fall's Church, Va.; concerning Camp Thomas, Chickamauga, Ga., with their pollutions of every possible class. The loss of life in these camps was more than forty times the corresponding loss in the city of Cincinnati, and one hundred times that of the City of New York (see "Purification of Public Water Supplies," J. W. Hill, p. 268).

The law should be so drawn that, without depriving the line officers of their proper military authority, yet it should fix definitely on whom this responsibility for the death and disability of the soldier by preventable disease rested; should fix when and under what conditions the Medical Department or the Line is responsible, or to fix it permanently on the one or the other. The law should fix the responsibility in order that some one man may be punished for the violation of established sanitary law.

No man, seeing before him the absolute certainty of having to account to the law, with his own body and reputation, for the loss of life, and for disease arising from his carelessness, lack of knowledge, lack of what not, will hesitate to apply the legal remedy and thus keep from his own shoulders the responsibility.

The saving to an army in suffering, to its individual men, to the Government in money paid in pensions, to the dependents of the dead, the disabled, and to men to replace the dead and disabled on the active lists is simply incalculable.

The cost to the individual soldier in suffering has been great from a lack of proper sanitary care. A careful examination of the medical histories of wars will show any man, who has made sanitation a study, what huge costs governments pay for a lack of sanitary law for their armies, and a fixing therein of the individual upon whom shall rest the responsibility for a breach of the sanitary law. Any military commander committing a military blunder which sacrifices his army is punished, but they are allowed to sacrifice men without number to insanitary conditions without question, without a word of condemnation, or even a thought of so doing.

TRANSPORTATION.

The other point to which I wish to call attention is the International Treaty, the so-called Geneva Convention, to which the United States is a party. This provides that all of the transportation and supplies of the Medical Department which go with the moving army, under its terms called "ambulances" (See Additional Articles, Article III, Geneva Convention), are exempt from capture and from being fired upon.

The greater part of these are under the control of the Line, and belong to the Quartermaster's Department, and are accounted for to this department. This condition makes all of this transportation liable to capture, and to be fired upon by the enemy, for they are unable to distinguish the transportation of the Medical Department (exempt) from that of the Quartermaster (non-exempt). This leaves medical transportation exposed to capture, etc., because unprotected by the International Treaty. (The Act of March 11, 1864, gives strict orders about ambulances, etc. The United States became a party to the Geneva Convention in 1882.)

The transportation of the Medical Department and many medical supplies were left at Tampa, Fla., by orders of the line officer when the army went to Cuba in 1898. The Surgeon-General should have had authority, and then he would have had the proper ship on hand, and would have moved all of his supplies and transportation on his own ship at the same time that the troops moved, and he would have had his material and transportation ready to disembark at the same time that the troops disembarked, and would have prevented the suffering that took place for the lack of this material and transportation when the fights took place. As it was, the comparatively small amount of material which the chief surgeon was able to take with the expedition was scattered throughout all of the ships of the expedition; he was compelled to devote much of his own time and that of other officers to try to get such portions of this medical property as was possible from the mixed mass of quartermaster, ordinance, commissary, and medical stores on board of these ships, instead of being able to attend to the proper distribution of both officers and supplies of his department.

The report of Captain E. L. Munson, Assistant-Surgeon, U. S. A., shows the exceeding difficulty which the medical department encountered in getting proper transportation for their supplies, showing that after much worry he obtained a four-oared boat, which was taken away from him after a few hours.

Should a field hospital be captured under present conditions, the first question by the enemy would be: "To what department does this material belong? Can the Line of your army take any of this material from the Medical Department and convert it to its own use, or is it exclusively for the use of the Medical Department?" The answer by our medical officer of necessity must be that "the axes, stoves, cooking utensils, hospital tents and all other tents, hospital flags and guidons, horse equipments, wagons, ambulances, mules, and horses, one and all belong to the Quartermaster's Department; that they were liable at any time to be taken by the Line, used by them for fighting purposes, and that the Line was the sole judge of when and for what reason this was to be done."

The enemy will very properly say that "you are sailing under false colors. We have no time for fine distinctions. We will take the whole outfit." Yet the

medical officer is ordered to go into the field with this transportation, which belongs to the fighting force and to protect it by flying the Red Cross flag of the Geneva Convention over it until such time as the fighting force may need it. It is a clear violation of this treaty to place in the field hospital (ambulance) material belonging to the fighting force. Yet in the armies of the United States the "ambulances" are composed of material which the Line is obligated to take from the use of the sick and wounded whenever its needs require that they should do so, for not even the hospital flag or hospital tent is the property of the Medical Department. In fact all the wagons, horses, tents, etc., which go to form an "ambulance" belongs to the fighting force, and it is only loaned to the Medical Department until such time as the fighting force needs it again.

The word "ambulance" is ordinarily used to express the idea of a wagon so prepared that it will carry a sick or wounded man comfortably. This word, however, when used in the Geneva Convention is given a distinct and very much enlarged meaning. For the 3d Article of the additional articles gives to it the meaning of a field hospital or other temporary establishment which follows the troops on the field of battle to receive the sick and wounded. Hence, our English cousins and many others say "ambulance wagon," which translates into the vernacular as "hospital wagon."

It was the evident intention of the Geneva Convention to protect the sick and wounded. The ambulance wagon, the so-called Red Cross wagon or ambulance, because it is marked with the red cross of this convention, should certainly not be the only part of the field hospital which is protected from being fired on and from capture. The four and six horse wagons, the tentage, beds, bedding, and food are just as necessary to the care of the field hospital, and is, in fact, a part of it. The ambulance brings the patient to the hospital, the wagons move the tentage, etc., from place to place; as the command moves the ambulance wagon moves the patient, the wagons move the hospital. So long as the transportation of the Medical Department belongs to the Quartermaster and is only loaned for temporary use to the Medical Department, will the Line have the right—in fact, the obligation—to take it from the use of the disabled and convert it to the use of the fighting force, when they deem it necessary. What line officer will hesitate for a moment to take the mules from the Red Cross ambulance itself and send them for ammunition, should he be hard pressed and others not available. They do not bear the Red Cross. Certainly they will not hesitate to use a wagon marked Q. M. D., U. S. Army. This will enable the enemy to comply with the Geneva Convention and strip the hospital of everything that is likely to afterward be of use to the fighting force. The Line can at its own volition take quartermaster's property away from the Medical Department.

GENEVA CONVENTION—ORIGINAL ARTICLES.

Article I.—Ambulances and military hospitals shall be acknowledged to be neuter, and as such shall be protected and respected by belligerents so long as any sick or wounded may be therein. Such neutrality shall cease if the ambulances or hospitals should be held by a military force.

Article IV.—As the equipment of military hospitals remains subject to the laws of war, persons attached to such hospitals cannot, in withdrawing, carry away any articles but such as are their private property. Under the same circumstances an ambulance shall, on the contrary, retain its equipment.

ADDITIONAL ARTICLES.

Article III.—Under the conditions provided for in Articles I and IV of the convention, the name "ambulance" applies to field hospitals and other temporary establishments, which follow the troops on the field of battle to receive the sick and wounded.

What are the laws of war concerning the misuse of this protection?

RESPONSIBILITY.

The appended bill does not take command from the Line, but it does compel them to assume the responsibility for insanitary conditions which may arise when they choose to ignore the sanitary recommendations made to them by the Medical Department, when they do so without proper military reason for their action, and it does provide a legal remedy whereby the officer responsible may be reached by proper legal process. To assume the responsibility with proper military reason is a thing that the Line should at all times have the right to assume. In such camps as Camp Thomas, Ga., there were strong reasons to carry out sanitary law and none to ignore them.

On page 2981-83 of the report of the commission to investigate the war with Spain, Col. Hartsuff (the chief surgeon at Camp Thomas, Ga.), testified that he personally reported to the General in command that one of the camps was "outrageously foul; that it was an imperative necessity that this camp be broken up at once; that there are large numbers of typhoid fever cases in each regiment." His letter was dated July 11, 1898. On page 2983 he testifies:

Question: "Practically, then, all the recommendations that you made were simply paper manifestoes?"

Answer: "In most cases; yes, sir."

On page 3080 the General in command testifies:

Question: "Had any of the wells, General, been condemned by the Medical Department prior to your leaving the department?"

Answer: "By alleged Medical Departments? Two of them were erroneous, I believe, after examination into it myself. . . . Another well lying on the road between the Alexander House and Jay's Mill was also condemned. I drank of that well water every time I passed it until somebody broke the pump to pieces. I suppose it was some of our energetic medical fraternity, who had spent their time in finding that there was a suspicion of these two wells, and then I did not bother further about it."

Either the medical officer or the officer in command was at fault. Unfortunately, there is no fixed responsibility before the law for either the one or the other, and so it is that no one is punished for this most culpable state of affairs, except the helpless soldier, whose love of country leads him to an inglorious death and a premature grave by diarrhea or dysentery, a death as useless as it is preventable and expensive to the United States.

The question, plainly put, is, How many men lost their lives in 1898-99 from the incompetency of the commanding officer, or of the medical officer? Of the officer who was to judge of the necessity of carrying out the recommendation made or of the officer whose duty it was to recommend? It must perforce lie between the two.

Army Regulations, 1895, paragraphs 1392-93, make the medical officer responsible for recommendations, but gives none to the commanding officer for not carrying out the recommendations made, but gives him the expressed right not to do so.

No medical man will continue to recommend when he sees his recommendation treated with good-natured indifference, or worse, for by so doing he lessens the influence that he may have; he does, however, continue to talk to the commanding officer and try to influence him in the right direction in spite of the indifference with which he is met. The medical officer is compelled to obtain what he can in a sanitary way by means of placation and persuasion.

In answer to the above there will be many responses, which, when sifted, simply mean that those in command are unwilling to assume responsibilities for matters which they do not understand; that they feel that they must have absolute and entire control of everything in the army, both in peace and war; otherwise the victory is not to be won, etc.; that no man should be allowed to tell them how to take care of the men; that they have done so in the past and that they can do so in the future.

If the medical man in the army is not competent for the responsibilities above sought, the sooner that he is removed and replaced by competent men from civil life the better for all concerned. It is far more important that the medical man should have ability to prevent the ingress of disease into a command than to be able to treat it after it has arisen.

Command has grave responsibilities. In order that it may be effective it must have absolute and unquestioned control of men and material present. Among these responsibilities is that for insanitary conditions that may arise. Line officers are not trained sanitarians, medical officers are. Under the present law neither is responsible. All errors are charged to military necessity, unfortunate, but non-preventable.

The Omniscient has established a law governing the life of the typhoid bacillus as certainly as he has fixed the path for the several planets. The law of germ disease and the law of sanitation, while certain, are delicate and difficult of comprehension and require years of study to comprehend even in degree.

The layman of the highest intelligence does not comprehend the full relation of cause and effect in matters of sanitation, or in the transplantation, growth and destructive effect of the typhoid bacillus without long study. He prefers to call to his own family an expert physician when his wife or child is sick, and he takes expert advice; but when he is an officer of the Line he sometimes—nay, often—regards such advice as an invasion of his superior authority, and disposes of it by writing across the written advice of the expert employed by the Government, the report and recommendation of the medical officer, "Not concurred in," which disposes of the matter.

It is a breach of military discipline to undertake to argue with the commanding officer or to instruct him in sanitary care, or even as to the habits of the typhoid bacillus. Thus soldiers die, are disabled, and huge sums are paid for pensions which could have been avoided. Is it not best to leave sanitary matters in the hands of medical men? Is it wise to leave them in the hands of the Line officer? I have conceived the idea that the purpose of Congress in creating the Medical Department of the United States army was that the Medical Department should direct such measures as would give the General, when he offered or was to receive battle, the greatest number of men in the best physical condition, and to watch over the men that the smallest amount of disease may arise, so that the greatest number may be returned to their homes fit to earn the living for the family when the war is finished, and that the fewest be compelled to accept the provisions of the pension law.

In other words, if the medical officer is to take care solely of the sick and wounded, and the Line officer is to look after the sanitary condition of the camps, barracks and troops, then the most valuable part of the medical officer's knowledge is lost. Certainly his best work is done in preventing disease, and not in caring for it after it has arisen from insanitary conditions imposed by the imperfect knowledge of the Line. To put it another way, there are many medical officers who wish far more strongly for the power to enable them to control disease than for any increased rank that may be given them. Certain it is that the people should dread a war far more for the preventable diseases that may arise than for injuries that may result, and perhaps more still for the taxes for pensions due to such cause.

Compare anywhere the sanitary conditions which exist where the Medical Department controls and where it recommends. Compare the hospitals in the city of Manila with the barracks of the troops of that city. Compare the hospitals where the Medical Department has the command and where it is subjected to the command of a Line officer.

The most important thing to be brought out is, that neither the commanding officer nor the medical officer is responsible under the present law and regulation for insanitary conditions which may arise with the resultant diseases and deaths, that this condition is a great wrong to the soldier and that it should be corrected by law. Neither the commanding officer nor the medical officer can be punished under the present law and regulations. It is my firm conviction that when a man causes the loss of another man's life, by inattention to his duty, or by faulty judgment of what his duty was, that there should be some legal process by which to punish him for his inattention, or to remove him for his lack of correct judgment. Under the present law and regulation the cry is the same old cry which sacrificed the medical man in the Crimean war. The general saying that the medical officer did not inform him of the conditions, that he did not make the proper recommendations, that he himself had made careful daily inspections, that he did not see the conditions complained of; therefore, he could not issue the orders to prevent things that he did not know of. The medical officer answers that he did report day by day to the general, that he made the recommendations, that he foretold that which happened, that the general thought that it was best to let matters take their course. Both claim that the other is responsible and the public can not know which truly is. This very plea was made before the war investigating commission in 1898, when the question was up as to who was responsible for the great spread of typhoid fever and the unnecessary loss of life therefrom. There should be a code of punishment provided for those actions which lead to the death of men from preventable disease without military necessity.

RESULTS.

The results of such regulation were plainly visible at Camp Thomas, Ga., at Camp Alger, Va., and other camps of assembly in 1898-99. Numbers of men lost their lives through some one's fault. Has the responsibility been fixed? No! It is impossible to fix the

responsibility under the present law and regulation. Such things should not be allowed in this day. The responsibility should be fixed on the medical officer, who is trained for this work, or it should be fixed on the Line, and it should be fixed by law. The principal thing is to fix the responsibility either on the Line or the Medical Department, but fix it so that it may not be evaded by any possible excuse, except that of military necessity in the face of the enemy.

The place *par excellence* to see the effect of this lack of law will be a classified list of the diseases and injuries for which pension has been granted, both for the Civil war and that of 1898-99. and a classified list of the claims yet to be adjusted. Take these lists to any man who is a sanitarian and ask him what percentage of the disease represented on the lists could have been prevented by a proper sanitary care, what percentage with good sanitary care would have left no permanent disability.

There is no man more earnestly in favor of the pension law than I am, but I do feel that it is far better to so treat the soldier that when the war is over he will return home in good physical and mental condition. To so return all but the killed and wounded would be perfection.

I do not wish to imply that the pension rolls have men improperly on them, but I do wish most emphatically to state that had the Medical Department had the power to control in sanitary matters a very large proportion of the deaths and disabilities from disease could have been prevented, and would have been.

The Line officer should have the power of command over his troops, but when he refuses to correct sanitary errors he should have a controlling and imperative strategical reason for his refusal. He should not be allowed to subject his command to insanitary conditions in time of peace, nor in time of war, knowingly, unless there be imperative strategic reason, which he could offer to his superior as a proper defense.

No good business man employs non-experts to supervise experts.

It is my belief that the army medical corps, as a body, cares more for the power to do its full duty to the army than it does for any increased rank or pay. In order to do its full duty to the army it must control in sanitary matters.

At present its sole function is advice and recommendation; its only power the mental strength of its individual officer, who sees the sanitary error, and his ability to persuade commanding officer to correct it.

The following table is taken from an abstract of the report of Reed, Vaughn and Shakespeare, on the origin and spread of typhoid fever in the military camps of the United States in the Spanish war in 1898, p. 193:

Command, Etc.	Number of Regiments.	Mean Strength.	Cases of Typhoid Fever. Certain.	Cases of Typhoid Fever. Certain and probable.	Deaths from Typhoid.	Deaths from all Diseases
1st Army Corps (Chickamauga)	22	27,380	2,912	5,921	344	397
3d Army Corps (Chickamauga)	17	20,568	1,741	4,418	417	469

Total number of probable cases of typhoid fever among these troops (p. 57) 9,660
Percentage of probable typhoid fever among these troops (p. 57) 21.56
Total number of deaths from typhoid fever among these troops (p. 57) 714

Mortality per 100,000 living from typhoid fever was as follows: First Army Corps, 1749; Third Army Corps, 2146.

J. W. Hill, "Purification Public Water Supplies," pp. 268-71, gives the following death-rate for typhoid fever: New York, 21; Chicago, 83; Philadelphia, 64; Cincinnati, 67; The Hague, Holland, 3; Cairo, Egypt, 260.

The above is calculated on all living in the cities; those for the army corps are for men in the prime of life, from 21 to 35, selected after a careful physical examination (see enlistment papers in the Adjutant-General's office, Washington, D. C.).

Notter and Firth, "Theory and Practice of Hygiene," published by Blakiston & Son, 1896, p. 772, gives the annual death-rate per 1000 living males for age groups:

Age group.	1871-80	1881-90	1891-93
20-25	7.4	5.7	5.4
25-35	9.4	7.8	7.4

Translating this to 100,000 living makes:

20-25	740	570	540
25-35	940	780	740

Death-rate per 100,000 living from typhoid fever alone in the army, the physical condition of the men vouched for at enlistment as sound, was as follows: First Army Corps, 1749; Third Army Corps, 2146.

On page 779 of Notter and Firth is given the follow-

ing as the death-rate from typhoid fever per 1000 living in England and Wales:

1884	0.236	1889	0.176
1885	0 175	1890	0.179
1886	0 184	1891	0.168
1887	0.185	1892	0 137
1888	0 172	1893	0.229

The following, showing the annual mortality from several sources per million persons living at all ages in successive periods and years, is taken from "Vital Statistics," by Arthur Newsholme, published by Swan, Sonnenschein & Co., London, 1899, p. 320:

	1861-70	1871-80	1881-90	1891-95
Typhus	885	57	14	4
Enteric (typhoid)		322	196	174
Ill defined		103	25	8

The following table ("Vital Statistics," p. 203) shows the attack-rate and death-rate per 100,000 living from typhoid fever for the entire population of the city of London at each age period in 1896 for the two sexes:

All ages.	Attack rate—Males.	Death rate—Males.
20	117	26
25	107	22
35	60	19

The report of Reed, Vaughn and Shakespeare, p. 94, gives the following data for Second Corps:

	Attack rate—Males.	Death rate—Males.
1st and 3d Army Corps, 1898	21,560	1,947
2d Army Corps, 1898	11,238	1,070

The mortality for the First and Third Corps together is about ninety-two times the corresponding loss in the city of New York, and twenty-eight times that of the city of Cincinnati, Ohio. The entire male population is included in the calculation for the cities. The First and Third Corps were men picked carefully for physical soundness less than six months previously. The attack-rate was about 184 times that of the city of London for 1896. The General in command of the Second Army Corps, in his testimony before the investigation commission, pp. 233-234, said: "I believe that the water, when it came from the wells, was as pure as when filtered; in other words, I would rather drink the water that came from the wells but I, of course, subordinated my opinions in those matters to my medical officers."

The General in command of the First and Third Corps says in his testimony, p. 3080, speaking of the water at Camp Thomas, Ga.: "Another well lying on the road between the Alexander House and Jay's Mill was also condemned. I drank of that well water every time I passed it until somebody broke the pump to pieces. I suppose it was some of our energetic medical fraternity who had spent their time in finding that there was a suspicion of these two wells."

Among the conclusions of Reed, Vaughn and Shakespeare are the following (pp. 178-188):

13. Typhoid fever is more likely to become epidemic in camps than in civil life, because of the greater difficulty of disposing of the excretions from the human body.

14. A man infected with typhoid fever may scatter the infection in every latrine in a regiment before the disease is recognized in himself.

15. Camp pollution was the greatest sin committed by the troops in 1898.

18. Many commands were allowed to remain on one site too long.

19. Requests for change in location made by medical officers were not always granted.

20. Superior line officers cannot be held altogether blameless for the unsanitary conditions of the camps.

As we have already seen, some of the regiments were improperly located from a sanitary standpoint. This was done by superior line officers, and sometimes in the face of protests from the medical officers. We have also seen that requests for change in location were disregarded, and regiments were allowed to occupy one site for too long a time. In general, the camps became very filthy. It must therefore be admitted, it appears to us, that line officers were to some extent responsible for the condition of the camps under their command. The medical officer can only recommend, the line officer can command.

21. Greater authority should be given medical officers in questions relating to the hygiene of camps.

In our opinion, it is of the greatest importance that more authority be granted medical officers in all matters pertaining to the hygiene of camps.

22. It may be stated in a general way that the number of cases of typhoid fever in the different camps varied with the methods of disposing of the excretions.

42. The continued fever that prevailed among the soldiers in this country in 1898 was typhoid fever.

At the second session of the Fifty-Sixth Congress, December 6, 1900, Mr. Hay introduced in the House of Representatives the following bill, which was referred to the Committee on Military Affairs and ordered to be printed:

A BILL.

To define the duties of the Medical Department of the Army of the United States.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the duties of the Medical Department of the army of the United States shall be as follows:

1. The direction of measures for the prevention of the ingress of disease among the troops of the army and of sanitary faults in location, construction (and management) of posts and camps.

2. The medical and surgical care of diseased and injured officers and soldiers of the army of the United States; the physical examination of all officers and soldiers entering or leaving the army of the United States.

3. The care (of) and accountability for all transportation pertaining to the movement of men and supplies of the Medical Department and (of) the sick and injured of the army.

4. The preparation and preservation of the records of transactions taking place under the three preceding paragraphs.

5. It shall be the duty of the senior medical officer of the (army), corps, division, or brigade (territorial division or department), in which an unusual outbreak of disease shall have arisen to at once take steps to investigate and determine the reasons therefor.

Should this investigation show any carelessness or inattention to duty, either upon the part of the medical officer or of the officer in command at the infected point, he shall at once make report (of the facts) to the officer in command (of the army, corps, division, or brigade, territorial division, or department), whose duty it shall then become to bring the offending officer or officers before a court-martial for such punishment as, upon conviction, the court may deem proper and the reviewing authority concur in.

6. The Secretary of War is hereby authorized and directed to prepare suitable regulations for the enforcement of the provisions of this act.

7. The Medical Department shall also perform such other duties as the President or the Secretary of War may deem for the best interest of the army.

All acts and portions of acts in conflict with the above are hereby repealed.

Should the ideas advanced in this paper meet with your approval, I most earnestly urge that you will take steps to have the public at large thoroughly informed on the subject. My object is and has been to obtain the best possible protection for the American soldier from preventable disease.

SATURDAY, OCTOBER 26, 1901.

DIAGNOSIS.

When called to a case, the young physician is apt to meditate more on what he shall prescribe rather than on what is the matter. As a student he was, perhaps, more diligently occupied in copying the pet prescriptions of his favorite teachers than in noting the care with which these same teachers sought to impress upon his mind the importance of diagnosis and the fact that a correct knowledge of the disease process, its cause and its natural course, must precede a rational therapy.

What the average practitioner thinks he wants, when, after a decade of practice, he attends a post-graduate school, is a knowledge of the new drugs and the latest method of treatment. He is satisfied with his ability to recognize typhoid fever, but has become discouraged because his last three cases died in spite of the treatment that had been so uniformly successful in scores of cases in years gone by. Had he made autopsies on his three cases perhaps he would have been surprised and shocked, and would have felt that his diagnostic, rather than his therapeutic, ability was at fault when he discovered no evidence whatever of typhoid, but an empyema in the one case, an ulcerative endocarditis in another, a tubercular meningitis in the third. Failure to make autopsies, lack of rigid criticism by consultants who are too prone to agree with the attending physician, and neglect of careful and repeated examinations in all cases that are atypical or in any way obscure, render a physician overconfident in his diagnosis; he often blames therapy where the fault is that he failed to understand rightly the nature of the disease.

The ability to make a correct diagnosis is not entirely the result of native genius. As Cicero said about the making of a poet, the natural ability is of great importance, but the man of surpassing merit is he who joins to his native talent the power that comes from education. The man of quick perception, of logical mind, and with acute special senses may make a rapid and apparently intuitive diagnosis. But in its ultimate analysis such a diagnosis is the result of study of books, and of experience at the bedside and in the laboratory; it implies weighing of probabilities and close logical reasoning; it is far from intuitive. This is the hard lesson to teach the young man who becomes discouraged as he ploddingly works over his case and still is unable to name the malady, or grows careless through his effort to work as rapidly as his preceptor or his superior. But practice in this line brings improvement as it does to the pianist, who soon reads and plays at sight music that was at first entirely beyond his grasp.

Many diagnoses are made with positiveness. When technique is faultless one may at times be able to pronounce a case tuberculous, or to declare the nature of a fragment of tumor, or the presence of fluid is proven by aspiration or a fracture recognized by crepitus, etc. Yet while the learned and trained physician is the most positive in his diagnosis when he is sure of his ground, no one is more cautious and guarded when positive signs are lacking, and no one more candid in saying, "I do not know." It takes some men many years before they attain that mental attitude commanding the wide horizon and giving them the clear vision so that they can look about and declare openly, "I do not know." Some men never reach this high plane; others lack the courage to confess what seems to be ignorance. But the intelligent layman who has tried his physician and not found him wanting, is willing to accept this confession of limitation of human power; he recognizes the feebleness of human insight into the workings of Nature, and he waits patiently until the physician is ready to announce his decision. The physician who is honest in his diagnosis has nothing to retract; he is not obliged to "hedge."

The physician who has had impressed upon him early the importance of diagnosis, who realizes the diagnostic ability is not a gift but an acquirement, and who gives his opinion not prematurely and guessingly, but conscientiously and after full deliberation, may not be brilliant, and may add little to the world's store of knowledge, but he goes about doing good; he commands the respect of his patients and his colleagues, and is free from the stings of conscience that come through mistakes committed through haste and carelessness.

THE DISTRIBUTION OF PHYSICIANS.

The recent census proves the source of not a few surprises in what concerns the distribution of physicians to the number of inhabitants in various parts of the country. It would not be surprising to find that doctors were most numerous in proportion to the population in the long-settled Eastern States. As a matter of fact this is not the case, however. California, Colorado, Kansas, Missouri, Iowa and Arkansas have more physicians to their population than any of the Eastern States except Vermont and Maryland. There are less inhabitants to each physician in Texas with its scattered population and magnificent distances than in Pennsylvania with its dense population, most of which is gathered into a few compact areas. Physicians are said to affect especially crowded centers of population, but some of these statistics would seem to contradict the old tradition and show that there is still a very large number of men who prefer a country life with its long, tiresome journeys to the pent-up city existence with its conveniences and social features, but absence of contact with nature.

With the exception of the District of Columbia, where, of course, many circumstances, such as political reasons, the glamour of fashion and of official life, and especially the presence of the medical headquarters of so many government departments, conspire to increase the number of physicians, California has more doctors to the population than any other part of the United States. The reputation of the State as a health resort is evidently responsible for this preponderance. Next after California in this matter comes Colorado, and for similar reasons. Physicians in delicate health are added to the practitioners who would naturally practice in the State, and, besides, graduates from a distance are attracted by the prospect of the superabundance of patients these States attract. For identical reasons Florida has distinctly a greater proportion of physicians to the population than any other Southern State.

It is evident from the census statistics that we must be rapidly approaching the limit of additions to the medical profession if the individual members are to find the practice of medicine a lucrative occupation. The New England States have an average of less than 600 inhabitants to each physician. New York has 596, while Pennsylvania provides 693 people for every doctor. New Jersey, with many health resorts but no medical school, and a rigorous examining board, has but one physician for every 881 inhabitants. The profession does not fare so well in the Middle Western States, where in Indiana there are but 519 people to each physician, in Ohio 529, in Michigan 575, and in Illinois 583. Meantime there are no special complaints of indigence among the members of the profession in California and the District of Columbia, though the number of inhabitants to each physician is respectively 392 and 389.

Curiously enough the distribution of the dentists of the country follows closely that of the physicians. They are thickest at the National capital, and after that in California. Colorado, for some reason not easy to understand, does not come third but is much lower in the list, the place being taken by Massachusetts. Utah has a very high place in the comparative number of dentists to the population, which would seem to show that the larger proportion of women in the State has led to the inevitable application of the rule of supply and demand. The prospects of making a living soon after graduation would seem to be still good in dentistry, the average number of dentists to the population of the country being only one to more than 4000 inhabitants.

HYPERTROPHY OF THE HEART.

Some new light has been thrown upon the manner in which the heart hypertrophies, and upon the causes that lead to cardiac hypertrophy both under physiological and pathological conditions, by the important work of Carl Hirsch.[1] Hirsch approached the problem in a somewhat different manner than previous observers; he employed more exact methods of study in that he separated the walls of the four cavities and considered each as an entity. This permitted the consideration of the relation of the mass of each cavity to that of the entire heart and of the general musculature of the body in health as well as in various diseases. It appears that the mass of the heart muscle is an expression solely of the work it accomplishes and that in sound individuals there is an intimate and direct relationship between the activity of the heart and the activity of the general musculature independent of conditions of general nutrition. Pregnancy was found to be of influence only in so far as it increased the activity of the muscles of the body as a whole. Glandular and nervous activity causes no direct effect upon the operations of the heart as expressed in its mass with the exception of exophthalmic goiter. Kaehl has demonstrated anatomically that the chief divisions of the heart are in reality quite independent of one another, and Hirsch shows that they are likewise independent functionally. Hypertrophy of one part may occur without any one of the other three parts participating. For example, in sclerosis of the thoracic aorta and splanchnic vessels the wall of the left ventricle is alone affected. On the other hand, in nephritis all sections of the heart are hypertrophied as a rule, a disproportional hypertrophy of the left ventricle being always due to vascular sclerosis according to Hirsch. In nephritis, however, the hypertrophy in incipient cases is limited more or less to the left ventricle, the other parts becoming hypertrophied as the disease progresses. Ewald suggests that in nephritis an increased viscosity of the blood is responsible for the hypertrophy of the heart, and since Hirsch's observations show that the obstruction to circulation must be of such character that the action of the whole heart is increased quite uniformly, Ewald's theory, although generally neglected, is considered by Hirsch to receive some support.

The opinion of Cohnheim that in weakness of the right heart the venous stasis may so increase the work required of the left heart that it may undergo hypertrophy, is widely accepted. But that this is the case Hirsch denies, citing in evidence cases in which there was protracted venous stasis without complicating valvular or arterial lesions and atrophy in place of hypertrophy of the left heart. This he explains by assuming that the accumulation of a large part of the blood in the vein lessens the amount of work that the left heart must do.

Another interesting observation is that in beer drinkers the hypertrophy known as "beer heart" indicates always an interstitial nephritis. Beer drinkers without nephritis have no hypertrophy of the heart.

In connection with these problems the study of the individual fibers in hypertrophied hearts by John Gutch[2] is of interest. He found that the increase in the size of the heart is to be explained by an increase in the size of

1. Deut. Arch. f. Klin. Med., 1899, lxiv, 597; 1900, lxviii, 55 and 321.

2. Jour. of Path. and Bact., 1901, vii, 309.

the individual fibers, and that there is no evidence of new formation of muscle cells. The fibers increase chiefly in breadth, possibly also somewhat in length. He corroborates the statements of Hirsch in regard to hypertrophy of both sides of the heart in nephritis. The fibers in the left side are usually larger than those of the right, and the papillary muscles have smaller fibers than the walls whether the heart is normal or hypertrophied.

JOURNAL OF THE ASSOCIATION OF MILITARY SURGEONS.

The first number (August) of a new medical magazine, the *Journal of the Association of Military Surgeons,* has just come to hand. It forms a volume of 224 pages, much of which in this issue is taken up with the proceedings of the association, lists of members, etc., though there are also several original articles. During the present association year it will be issued quarterly, but it is the intention to ultimately adopt the monthly form, and to devote the space in future issues more fully to original contributed matter. The *Journal* occupies a hitherto unfilled niche in American medical journalism and it has our cordial wishes for its success. The list of the membership of the association it represents shows that it starts with what ought to be a very respectable assured patronage. It is under the able editorial management of Dr. James Evelyn Pilcher, Captain (retired), U. S. A.

THE PATHOLOGICAL INSTITUTE OF THE NEW YORK HOSPITALS.

The Pathological Institute of the New York State Hospitals is being reorganized under the auspices of the state commission in lunacy, which has appointed an advisory board of leading specialists in psychology, general biology, pathology, neurology, psychiatry, etc. The appointees represent the three university medical schools of the city of New York, namely, Cornell, Columbia and Bellevue, and also the asylums. The appointments are permanent, except those from the asylums, which are elective for a term of two years, thus permitting all the institutions to be represented in rotation on the board. It is the idea in the reorganization to utilize the institute for special instruction of the asylum staffs in psychiatry and research methods, as well as to encourage original work in the various sciences having a bearing on insanity. It is, therefore, to have its future location in connection with one of the divisions of the Manhattan State Hospital on Ward's Island until such time as a reception hospital for the insane can be provided. The advisory board includes Professor J. McKeen Cattell of Columbia University, Professor Ewing of Cornell University, Professor Herter of Bellevue, Dr. Henry Hun of Albany, Dr. Hermon C. Bumpus of the American Museum of Natural History to represent the department of general biology, Drs. Pilgrim and Macdonald representing the state hospitals, and Dr. Frederick Peterson ex-officio as president of the lunacy commission. With this advisory board and a competent working staff who will be selected, we shall look for first-class work from the institute. Its success will, we trust, incite other States to follow the example of New York, and it is to be hoped it will cause a marked advance in the appreciation of American psychiatry throughout the world.

A CAUTION TO MEDICAL WRITERS.

We had occasion to call attention editorially not long since to a method of reporting experimental work that seemed objectionable, as affording a chance for certain individuals to misconstrue facts and misrepresent and slander our profession. The special instance was then afforded by one of our English contemporaries; now we have a similar one among our domestic exchanges. A writer in the New York *Medical Record* of October 19, describing some disinfecting experiments, uses the following language: "Then followed a rest of several weeks, our victim going out of town. On his return, culture testing still proved that the staphylococcus pyogenes aureus was present, but guinea-pig inoculations showed it to be of lessened virulence." Here is material for the anonymous writer of the Humane Society, or that section of it that is proving the atrocities of human vivisection, to dilate upon. "Our victim" had, as the report shows, undergone finger scrapings and loss of pieces of skin; he had been scraped and skinned, as the humane individual could say, and this would afford all the text required for any amount of virtuous horror at such an instance of human torture. It would, of course, not be necessary for such purposes to quote the context, and any medical explanation of the facts could be ruled out as coming from those disqualified as being, in sympathy at least, participants in the outrage. Medical writers should be more careful and not expose themselves in this manner when the antivivisection wolf is about searching for such titbits to devour.

LEPROSY AND THE MOSQUITO.

The spread of leprosy in the Hawaiian Islands is attributed to some extent to the mosquito by the local health authorities. There are cases that occur that are otherwise unaccountable, a fact that will hardly increase the mental quietude of those who are mosquito bitten in a country where leprosy exists. Of course, this mode of infection must be extremely rare, for mosquito bites are common, and these unaccountable cases are few in number. It seems probable that the indictment against the mosquito will be, as time elapses, a much heavier one than has been as yet conceived; it is the most efficient little inoculating machine that was ever contrived, and it seems to have a constitution suited to take up and carry about a number of uncomfortable things for the human species. It is said that it did not exist in some at least of the Pacific Islands originally, but was introduced after their discovery by white men. Herman Melville, in one of his works that is not altogether fiction, attributes its introduction to the Society Islands to a whaler, who, out of spite against some natives, landed a cask of larva-breeding fresh water on one of the islands. If this is true it has turned out to be a veritable Pandora's box to the natives, with far greater possibilities of evil than he in his malice designed. At present malaria, leprosy, elephantiasis and probably other mosquito-borne diseases

prevail locally or universally in the islands, and it would be an interesting study to trace up their medical history in all the different groups so as to determine how far the contact with civilization has been their causal factor.

INFECTION OF THE URINARY BLADDER FROM THE INTESTINE.

We have on a previous occasion[1] referred to observations made by Dr. R. Faltin with regard to infection of the urinary bladder in connection with disorders of the rectum. In order to determine whether such infection is a local process that takes place through the intermediation of the lymph stream or is merely part of a general process through the intermediation of the circulation Faltin[2] undertook a further experimental investigation, as a result of which he concludes that coprostasis induced by occlusion of the anus of from thirty-six to forty-eight hours' duration is not sufficient in general to cause an inundation of the body with intestinal bacteria. After artificial coprostasis of sufficiently long duration such changes in the intestine may take place that intestinal bacteria may gain entrance into the circulation either directly or through the intermediation of the peritoneum. Elimination of bacteria through the kidneys is possible under such conditions, but like the bacteremia itself it is to be looked upon as an antemortem process. Transitory bacteremia can not be produced. Following coprostasis of sufficiently long duration, intestinal bacteria may appear in the urinary bladder without first having entered the circulation. Under these circumstances such alterations in the organism have generally taken place that subsequently general infection, probably originating from the injured intestine or the bladder, often results. The bacteria in some cases gain entrance into the bladder by way of the urethra, in other cases probably by a direct route along the lymph paths, but whether through the lesions of the urethral mucous membrane or through injuries in the anal region has not yet been determined. Should retention of urine exist or have existed in consequence of ligature of the urethra, the presence of bacteria in the bladder is more frequent and cystitis may develop. It is pointed out that the foregoing conclusions are applicable only to experiments on rabbits, and it is not maintained that absorption of bacteria from the intestine and elimination of bacteria through the kidneys from any cause are in man always antemortem processes. While probably this is often the case, many clinical observations, as for instance in cases of typhoid fever, indicate clearly that bacteria may be absorbed from the intestine and eliminated through the kidneys without death necessarily following.

Medical News.

ALABAMA.

Smallpox.—The Health Officer of Jackson County reports 14 cases of smallpox among negroes at Hollywood.

The Medical College of Alabama, Mobile, opened October 12 with an address by the dean, Dr. George A. Ketchum.

Health of Montgomery.—The report of the Sanitary Department of Montgomery for the fiscal year shows a marked decrease in the cases of diphtheria and smallpox, and an increase in scarlet fever, as compared with the previous year. The total number of scarlet fever cases was 151, all of mild type. During the current year 6 cases of diphtheria and 13 cases of smallpox were reported, the respective figures for the previous year having been 14 and 268.

ARIZONA.

Personal.—Dr. Oscar Brandon, Nogales, has located at Naco.——Dr. F. L. A. Hamilton has moved to Nogales from Wagoner, Ind. Ter.

"Manila Itch" is said to be almost uncontrollable in the Gila Valley, at Solomonsville, Safford and other Mormon settlements. The disease was at first diagnosed as smallpox, and under rigid restriction and quarantine, soon disappeared. When, however, a "health officer" discovered that the disease was not smallpox, the restrictions were relaxed with the usual results.

Restriction of Tuberculosis.—The governor of Arizona intends to recommend the creation, under legislative authority, of a Territorial Board of Health, investing its officers with full power to quarantine and segregate persons coming into the territory afflicted with consumption, precisely along the lines of the power of the boards of health of the various states in quarantining against any dangerous contagious disease, and that a law be passed prohibiting consumptives from living in hotels and boarding-houses with well people, and requiring them to live upon the desert in such places or sanitariums to be provided, and in such localities where the possibility of contagion will be as greatly reduced as circumstances permit.

Campaign Against Tuberculosis.—The city council of Phoenix has passed ordinances to protect the public from tuberculous patients and prevent the spread of tuberculosis. The first of these provides for the placing of cuspidors or proper receptacles at street crossings and at parks, under the direction of the health officer, which shall contain disinfectants, and the second order that each room in a hotel, lodging-house or private residence, left vacant by a sufferer of consumption, shall be properly disinfected. A charge will be levied against the proprietor, or those who receive invalids, for each consumptive accepted, the sum to be applied to the fumigation of the room when the occupant leaves.

CALIFORNIA.

Smallpox and typhoid fever are reported from Walnut Grove, Sacramento County.

Dr. Thomas Howlett, formerly interne at St. Mary's Hospital, San Francisco, has been appointed resident physician at Dr. Clark's hospital, Gilroy.

University of California Medical School.—The Board of Regents of the State University has decided to take over the entire management of the medical school which heretofore has been only one among several medical and so-called medical colleges of the state.

COLORADO.

Dr. David I. Christopher, Colorado Springs, has been appointed house physician for the National Printers' Home at that place.

A physicians' business league has been organized at Victor, comprising membership from all over the district. It is for the purpose of social and intellectual intercourse and for the special advantage of the medical fraternity in protecting themselves against bad debtors.

Denver Diphtheria Deaths.—In the six years from 1889 to 1894, inclusive, before antitoxin was employed, 2272 cases of diphtheria occurred in Denver, with 827 deaths, a mortality of 36.4 per cent.; during the following six years since antitoxin has been in use, 1641 cases occurred, with 175 deaths, a mortality of 10.66 per cent.

Diphtheria, Scarlet Fever and Smallpox.—During September there were reported to the State Board of Health, 105 cases of diphtheria, 102 of scarlet fever and 15 of smallpox. Compared with August, these figures show an increase of 34 cases of diphtheria, and a decrease of one case of scarlet fever and 37 cases of smallpox.

Crusade Against Unlicensed Practitioners.—The State Board of Medical Examiners has obtained warrants for the arrest of Drs. Albert L. Bennett and J. Sterling Johnson, regulars; John T. Bass, Elizabeth C. Bass and H. Van King, osteopaths, and J. Howard Hiltz, magnetic healer, on the charge of practicing without having presented to the State Board of

Medical Examiners any diploma as a graduate of medicine; without having furnished any other evidence of graduation from a medical school; without having complied with the medical practice acts of 1881 and 1885.

CONNECTICUT.

Hospital Site Vetoed.—The mayor of New Haven has returned without his approval the order establishing a hospital for contagious diseases at Springside on account of its distance from the city.

In Memoriam.—At the semi-annual meeting of the Hartford County Medical Society, held October 16, obituaries on the following deceased members were pronounced: On Dr. George C. Jarvis, Hartford, by Dr. Horace S. Fuller, and on Dr. Sidney R. Burnap, Windsor Locks, by Dr. Joseph A. Coogan.

Dr. Patrick J. Callaghan, Waterbury, arrested on the complaint of the county health officer, on the charge of practicing medicine without a license, and fined $100 and costs, has appealed, and intends to test the validity of the state law. Dr. Callaghan's offense is that he had not registered with the county health officer as required by the medical practice act.

Personal.—Dr. Henry S. Noble has been elected superintendent of the Connecticut Hospital for the Insane, Middletown, vice Dr. Charles W. Page, resigned.——Dr. John E. Martin has suceeeded Dr. Lawrence M. Cremin as attending physician at the New Britain General Hospital.——Dr. P. Frederick Metz, New Haven, charged with malpractice, will not appear for trial; he has forfeited his bond and left New Haven.

DISTRICT OF COLUMBIA.

District Diseases.—Diphtheria is on the increase in the District; 60 cases are in isolation in 33 houses. Of scarlet fever there are 23 cases, and of smallpox 9 cases.

Personal.—Drs. John W. Mitchell and William H. Hughes, both of Washington, have been appointed assistant surgeons in the Freedmen's Hospital.——Dr. Benjamin B. Wechsler, Washington, has located in Knoxville, Tenn.——Dr. A. L. Swain, Washington, has moved to Athol, Mass.

Ask Adequate Remuneration.—The Board of Medical Supervisors of the District in its annual report calls the attention of the Commissioners to the fact that no provision is made for the adequate compensation of the various boards of medical examiners, or of the Board of Medical Supervisors. The members of these boards perform their duties solely in the interest of the public, and, under existing law, receive for their services whatever happens to be left over from the fees paid by applicants for licenses after the necessary expenses of the board have been deducted. No member of the board of eclectic medical examiners has received a cent for his services. The average amount received per annum by each member of the board of homeopathic medical examiners has been $1.75; by the lay members of the Board of Medical Supervisors, $20, and by the members of the Board of Medical Examiners, $32.14. The total number of applications is 1559, and the total number of licenses issued is 1411. It therefore requests that provision be made to pay each member of the Board of Medical Supervisors and each member of the Board of Examiners $10 for each meeting attended.

ILLINOIS.

Smallpox.—Springfield now has 31 cases of smallpox, and cases have also been reported from Riverton and Rochester.

The De Witt County Medical Society has passed a resolution that no physician shall be eligible to membership unless he has practiced medicine in the county one year.

Physicians' Club Reception.—Drs. John H. Mannon and Charles W. Hall, who have recently returned from Europe, were given a reception by the Physicians' Club of Kewanee, October 11.

Hospital Addition Postponed.—Although more than $6000 has been subscribed for the addition to the Rockford City Hospital, it has been determined to postpone building until next spring and to devote the winter to the completion of the fund necessary for the erection of the building.

Personal.—Dr. Lewis A. McFadden, Peoria, a member of the board of aldermen, has been appointed Health Commissioner, vice Dr. William T. Sloan, resigned.——Dr. Robert E. Calhoun, Chesterville, is taking post-graduate work in Chicago. ——Dr. Arvid E. Kohler, Moline, is seriously ill at the Baptist Hospital, Chicago.

Moline Hospital Troubles.—The Moline Public Hospital staff has unanimously adopted resolutions asking the mayor to remove the present board at once, and in its place appoint a board of three physicians. Also to appoint an advisory board, to consist of physicians who shall be made regular members of the board as soon as the law can be changed by the legislature, making the board legally consist of seven members, instead of three, as at present.

St. Francis' Hospital Staff.—The medical staff at St. Francis' Hospital, Peoria, consists of Dr. Rufus A. DuMars, president; Dr. Ernest B. Studer, secretary, and Drs. Charles E. Davis, Alvin N. Keith, Frank C. Bourscheidt, Clifford N. Collins, Lewis A. McFadden, William H. Willis, Roland L. Green, Joseph V. Studer and Joseph J. L. Finnell. Dr. Edwin H. Bradley is the oculist, and Drs. Joseph Studer and Leonard H. Spalding comprise the consulting staff.

Chicago.

Medical Examiners Dine.—The medical examiners of the New York Life Insurance Company held a conference and dined together, October 19. Dr. Harry P. Woley presided, and among the topics discussed were family history, venereal disease, albuminuria and appendicitis.

To Avert Smallpox.—With a view to prevent the importation of smallpox, Chief Medical Inspector Dr. Heman Spalding, of the Department of Health, is visiting neighboring towns and aiding the local authorities to check the disease. He has recently visited Harvey and New Holland, Ill., and Michigan City, Ind.

"Passing-up" Prohibited.—President Harper welcomed 275 Rush medical students, both freshmen and sophomores, into the University of Chicago at Kent Theater, October 15, and then officially informed them that hereafter "passing-up" students and other ungentlemanly conduct in the lecture-rooms would not be tolerated.

University of Chicago Medical Club.—The first meeting of this Club, a medical society organized by the University of Chicago, was held at the Hull Physiological Laboratory, October 21. A paper was read by Dr. Jacques Loeb, on "The Influence of the Valency and Possibly the Electrical Charge of Ions Upon Their Antitoxic Effects," and one by Dr. Albert Peacock on "A Case of Myiosis in Man."

St. Gerard's Hospital, established a year ago, is insolvent, and a receiver has been appointed. The liabilities are said to be $8300 with assets of $2400. The plan of the projectors of the hospital was to care for as many charity patients as the patients who pay could support. For several months the charity patients exceeded in numbers those who could afford to pay and the hospital's affairs grew worse constantly. The income was far insufficient and contributions practically stopped.

The Lowest Death Rate.—A total of only 370 deaths from all causes recorded last week establishes the lowest weekly death rate in the annals of the Health Department. The mortality is at the annual rate of 10.95 per thousand. The lowest rates during the previous five years were 11.04 for the week ended Nov. 10, 1900; 11.28, week ended Oct. 29, 1898; 11.72, week ended Nov. 27, 1897; 12.12, week ended Nov. 25, 1899; and 12.20, week ended Nov. 7, 1896—an average of 11.67, or 6.5 per cent. higher than last week's rate. This marvelously low figure is due chiefly to the decrease of deaths from apoplexy, bronchitis, cancer, consumption, convulsions, heart disease, nervous diseases and pneumonia—there being 31 fewer deaths from consumption alone and a total of 71 fewer from the diseases specified than during the previous week.

INDIANA.

Hammond Hospital and Training School has been incorporated at Hammond by Dr. John C. Pannenborg and others, with a capital stock of $10,000.

Diphtheria is so prevalent at New Albany that the Board of Health has ordered the schools to be closed, and all public meetings to be interdicted. The disease has reappeared at Knox.

Typhoid Fever.—There are 16 cases of typhoid fever at the State Reformatory, Jeffersonville, due in the opinion of the secretary of the State Board of Health to infected water supply.

Smallpox.—The situation at Mooerstown is improving rapidly.——Six cases have been reported from School District Number 1, Wabash Township, Adams County, and the public school in that district has been closed.

Medical License Cases.—Drs. W. F. Reinhardt and E. N. Flint, Indianapolis, have appealed from the decision of the

State Board, refusing them licenses.——Dr. George McD. Ober, Indianapolis, was arrested at Madison, October 11, for practicing without a license.——The Appellate court has modified its mandate in the action to revoke the physician's license held by Dr. Jacob B. Oliver, Brazil, so as to direct that a new trial be granted and further proceedings be had not inconsistent with the recent decision of that court reversing a judgment in Dr. Oliver's favor.

Expelled.—At a meeting of the Knox County Medical Society at Vincennes, October 14, Dr. Thomas H. Maxedon was expelled from the Society on the allegation of unprofessional conduct. The charges on which this action is based are that Dr. Maxedon sought notoriety in the newspapers; that he instituted suit against his fellow-practitioners, and that he recently gave improper testimony in a trial. Immediately after the expulsion, Dr. Joseph F. Somes resigned as a member of the Society. Dr. Maxedon claims that the action is summary, and that the charges are due to professional jealousy, and says that he will appeal for redress to the State Board.

Mortality in Indiana.—The reports to the State Board of Health for September show 2825 deaths, a rate of 13.6 per 1000 per annum. This is a decrease of 107 as compared with the preceding month and a decrease of 296 as compared with the corresponding month of 1900. All the cities in the State, with a population of 847,302, report 1052 deaths, which is a rate of 15.1 per 100,000. This exceeds the rate for the whole state by 1.5, and compared with the preceding months is a decrease in the rate of .4. The number of deaths classified according to important ages in the cities, was, under 1 year of age 221, 1 to 5, inclusive, 89, 65 and over 219. The country deaths numbered 1773, a rate of 12.9 per 100,000, which is 2.2 less than the city rate. The death rate from pulmonary tuberculosis in the country was 121.3, and for the cities 141.1 per 100,000. The typhoid rate for the country was 98.6, cities 76.3. The diphtheria rates, rural and urban, were 12.4 and 27.3 respectively. The diarrheal rates were, rural, 177.6; urban, 162.7; puerperal fever shows a rural rate of 2.9 and an urban rate of 4.3. This reverses the usual order. The cancer rate was, rural 46.7, urban, 59. Only in typhoid fever and diarrheal diseases does the rural rate exceed the urban. Tuberculosis caused the greatest number of deaths, 296; of these 264 were from pulmonary tuberculosis. The deaths from typhoid fever numbered 188; diarrheal diseases, 356; diphtheria, 36; scarlet fever, 4; whooping cough, 16; pneumonia, 73; cerebrospinal meningitis, 17; influenza, 4; puerperal fever, 7; cancer, 105, and violence, 113.

MARYLAND.

State Examination.—The State Board of Medical Examiners will hold the semi-annual examinations for license to practice medicine at the Medical Hall, Baltimore, November 6 to 9. The subjects are anatomy, physiology, surgery, hygiene, practice, pathology, chemistry, medical jurisprudence, materia medica, therapeutics, obstetrics and gynecology. A fee of $10 must accompany each application.

Baltimore.

Dr. Edmund G. Waters, while visiting a patient, October 18, fell down a stairway and fractured his left leg.

The mortality for the week ending October 19, was 177, or 17.77 per 1000 per annum. The white rate was exactly one-half of the black.

Yale's Bicentenary.—On October 22, at the bicentennial celebration of Yale University, Professor Wm. H. Welch, of this city, delivered an address on "Yale in Its Relation to Medicine," and Dr. Daniel C. Gilman, one on "Yale in Its Relation to Science and Letters."

Personal.—Dr. Jose L. Hirsh has returned from his wedding trip.——Dr. Charles E. Simon has returned from summering in Nova Scotia.——Dr. Jessie E. Sweet, who has completed a course at the Presbyterian Eye, Ear and Throat Charity Hospital, has returned to her home, Pine Bluff, Ark.

Detention Hospital.—Mr. Jeffrey R. Brackitt, president of the Board of Charities and Corrections, recommends the establishment of a temporary place of detention for emergency insane cases in the central part of the city. Attention was called to such a provision by the death of an insane patient shortly after being committed to jail last July.

St. Joseph's Hospital Annex.—The $30,000 annex to St. Joseph's Hospital will be opened November 5. The fund for its erection was raised by the Ladies' Auxiliary. It will accommodate about 75 patients, bringing the total capacity of the institution to 275. A steam laundry and a crematory for the burning of bandages, dressings, etc., have been installed. The addition will contain two negro wards and ten private rooms. It is in the rear of the main building.

Tablet to Professor Martin.—A large and beautifully framed bronze tablet to the memory of the late Professor Henry Newell Martin has been erected in the corridor of the biological laboratory at Johns Hopkins University. It bears this inscription: "In Commemoration of Henry Newell Martin of Neury, Ireland, A Graduate of the Universities of Cambridge and London, Fellow of the Royal Society, the First Professor of Biology and of Physiology in This University. By his brilliant work as investigator, teacher and author, he advanced knowledge and exerted a wide and enduring influence. Appointed in 1876. Resigned in 1893. Born in 1848. Died in 1898." A memorial meeting to the late Professor Henry A. Rowland, of the same institution, will be held in the physical laboratory, October 26, when Dr. T. C. Mendenhall, former president of the Worcester Polytechnic Institute, will make the address.

MASSACHUSETTS.

School Inspection in Worcester.—Dr. John T. Duggan, Worcester, chairman of the committee appointed to consider the matter of medical inspection in the public schools of that city, has asked for an appropriation of $3000 for that purpose.

West Roxbury Hospital.—Through the liberality of Abby L. A. Faulkner, Jamaica Plain, a hospital is to be erected and devoted to the care of the sick in the section of Boston known as the old town of West Roxbury. The buildings are to cost about $100,000.

Tuft's College Medical School.—The formal opening of the new medical and dental building of Tuft's College, Boston, took place October 3. President Elmer T. Capen, presided; Dr. Frederick W. Hamilton, chairman of the executive committee of the trustees, presented the building to the medical and dental faculties, and Dr. Harold Williams, dean of the schools, made the address of acceptance.

Personal.—Dr. Francis E. Corey, Westboro, has moved to Redlands, Cal.——Dr. Frank A. Foster, Waltham, has disposed of his practice and moved to Newton.——Dr. Leslie H. Hendee, Palmer, has moved to Westfield.——Dr. Homer Connor has opened an office in Haverhill.——Dr. Francis Shaw, Worcester, has located in Somerville.——Dr. and Mrs. Charles Hale Cogswell, Boston, intend to spend the winter in travel.

MICHIGAN.

Virchow.—The Detroit Medical Society has sent a congratulatory cablegram to Dr. Rudolph Virchow.

Smallpox Fees.—The Calhoun County Medical Society has fixed the fee for attending smallpox cases at $10 a visit.

Personal.—Dr. J. W. Toan, Otsego, has moved to Grand Rapids.——Dr. T. Bennett Scott, Vernon, has sold his practice to Dr. Louis Fleckenstein, Port Hope, who is now taking a post-graduate course in Chicago.

Card Catalogue of Graduates.—The secretary of the medical faculty of the University of Michigan, Dr. G. Carl Huber, has prepared a complete card catalogue of the alumni and alumnæ of the medical department.

Hospital Site Accepted.—The Hospital and Home Association of Port Huron has accepted Charles Baer's offer of a hospital site of three lots, and $1000 in cash toward the erection of a new hospital building. It will be necessary to raise $20,000 by popular subscription.

MINNESOTA.

Diphtheria is reported in St. Paul and Sletten.

Licensed to Practice.—The State Board of Medical Examiners, on October 11, issued licenses to practice to 19 candidates.

Swedish Hospital.—The cornerstone of the new Swedish Hospital, Minneapolis, was laid with appropriate ceremonies, October 6. The building is to be three stories high and will cost about $40,000.

Compulsory Vaccination.—Until the Supreme court decides otherwise, not a child will be admitted to the public schools of St. Paul until it has been furnished the required certificate of vaccination. This dictum of Dr. Justus Ohage is being combatted by the local anti-vaccination society. In St. Paul fully 2000 children are not attending school on account of failure to comply with the requirements of the Health Department.

Smallpox.—Smallpox exists at Slayton, Murray County, and at Gary, Norman County.—There have been many deaths

among the Indians in Mille Lacs County.——The disease is reported among the scattering bands of non-reservation Indians who roam about the vicinity of Sandy Lake, north of Aitken and McGregor.—Six cases were reported in Minneapolis in a Polish settlement in one day.——Several cases have been reported at Pelican Rapids and the public schools at that place have been closed.

Owatonna Hospital.—The Owatonna Hospital Board has passed a resolution that each patient shall be furnished by his attending physician with a certificate of his condition, on a form to be furnished by the hospital board, which certificate shall be given to the superintendent upon admission to the said hospital; and that the said certificate shall show that at the time of admission the patient is not suffering from smallpox, diphtheria, measles, scarlet fever, or pulmonary tuberculosis, all which cases are barred from admission to the hospital.

Personal.—Dr. Joseph G. Skaro, Minneapolis, is critically ill with nervous exhaustion in a hospital in that city.——Dr. John R. Petersen, Madison, is taking a post-graduate course in Philadelphia.—Dr. George G. Eitel, Minneapolis, is studying in Berlin.——Dr. James B. White, Montgomery, is about to locate in Faribault.——Dr. Ernest Z. Wanous, Rochester, has returned from a month's trip to the Atlantic seaboard.——Dr. Devereaux, Minneapolis, has located in St. Cloud.——Dr. H. C. Stuhr, Crookston, has opened an office in McIntosh.——Dr. Frank C. Davis, Minneapolis, is taking post-graduate work in Berlin.

MISSOURI.

Epidemic Disease.—Smallpox is reported at Cawood and Kansas City; scarlet fever at Hartville, Springfield, Ozark and Billings, and diphtheria in Springfield.

Marion-Sims-Beaumont Laboratory.—The new laboratory of the Marion-Sims-Beaumont Medical College, St. Louis, is now ready for occupancy. Dr. Meade Bolton, of Johns Hopkins University, has been elected director of the laboratory.

Personal.—Dr. Charles B. Lawrence, Stet, has moved to Woolstock, Iowa.——Dr. John Powers, Urich, has located in Clinton.——Dr. Thomas J. Halsey, Triplett, Chariton County, has moved to Drexel.——Dr. R. S. Bennett, Drexel, will spend the winter in study in New York.

Dr. James A. Manahan, Kansas City, assistant city physician, who was summarily discharged by the mayor, a few days ago, claims that the mayor has no authority in the matter, and that only the city physician, Dr. George O. Coffin, has the right to discharge him. He accordingly reports for duty as usual.

Virchow Banquet.—On October 13, one hundred and ten physicians and scientists met at St. Louis, at a banquet held in honor of the eightieth birthday anniversary of Rudolph Virchow. Dr. Robert Luedeking presided. Addresses were delivered by Dr. Hugo Summa on "Rudolph Virchow"; by Dr. Willard Bartlett on "Virchow the Pathologist"; by Dr. Amand N. Ravold on "What Hygiene Owes to Virchow"; by Dr. Robert Terry on "Virchow's Work in Anthropology"; by Mr. Charles Nagel on "Virchow as a Public Man," and by Mr. Perry Post Taylor on "Medicine as a Cosmopolitan Science."

NEW JERSEY.

Diphtheria is prevalent in Bloomfield, where 18 cases have been reported, and Brookside school has been closed for fumigation.

The Lost Hospital.—Crawford had an isolation hospital last spring. It was a substantial wooden building, 22 by 22 by 10 feet. A few days ago the chairman of the Board of Health went to inspect the hospital and could find no trace of it.

Panic in Hospital.—Fire caused a panic in the Paterson General Hospital, October 8, which might have been attended with serious results but for the coolness displayed by the superintendent and nurses. The patients were promptly removed and the fire extinguished.

Hospital Changes.—Dr. Norman L. Rowe, whose term as house surgeon at Christ Hospital, Jersey City, expires November 18, will be succeeded by Dr. Souloff. Dr. Darling has been appointed ambulance surgeon.——Dr. W. J. Hickson, resident physician of the Atlantic City Hospital, has resigned.

Dr. D. Warren Poor, East Orange, has been appointed medical inspector of the Orange public schools. His duties consist in responding to the call of the superintendent, examining suspects, and if he finds them afflicted with an infectious or a contagious disease to send them home with instructions to consult a physician. It will not be his duty to treat the cases. For more than a year Dr. Edgar C. Seibert, president of the board, has been urging the necessity of inspection, and Dr. M. Herbert Simmons one of the commissioners, and Superintendent William M. Swingle have ably seconded his endeavors.

Endorsement of McKinley's Physicians.—Dr. Charles F. Lehlbach, Newark, secretary of the Practitioners' Club of that city, has transmitted the following preamble and resolutions: "The Practitioners' Club of Newark, N. J., at its regular session, October 7, 1901, desires to express its highest appreciation of the courage, skill and professional ability displayed by the physicians in attendance upon the late President William McKinley: Be it therefore resolved, that the club regrets exceedingly that so unjust, uncalled for, unfair and arrogant a criticism should be made as appeared in the *New York Medical Record* of September 21, and hereby expresses its indignation and disapprobation. The club resolves furthermore, that a copy of this resolution be forwarded to the publishers of the *Medical Record, American Medicine,* and THE JOURNAL of the American Medical Association.

NEW YORK.

Personal.—Dr. Myron W. Hunt, Holland Patent, has located in Canastota.——Dr. Charles B. Sprague, Pottersville, will take a course of post-graduate study in New York City.

Elmira Isolation Hospital.—The health authorities of Elmira are having difficulty in obtaining a site for their isolation hospital. There is urgent need for such an institution, as a few cases of smallpox still exist in the city.

To Enforce the Ordinance.—A crusade against delinquent physicians who fail to make official reports of the cases of pulmonary tuberculosis which they are called to attend has been decided on by the health bureau and law department officials of Rochester.

New Rochelle Hospital Troubles.—The medical staff of the hospital at New Rochelle has resigned because the board of governors has passed a resolution making their terms only one year. The ten leading physicians of that city formed the medical staff. They say it was agreed that once a physician was appointed to the staff he should enjoy a perpetual tenure of office.

New York City.

New Harlem Hospital.—The Board of Estimate has authorized a bond issue of $275,000 for the construction of a hospital in Lenox Avenue between 136th and 137th streets, to be known as the New Harlem Hospital.

Merchant Marine Hospital Service.—Dr. William T. Jenkins, who has been in Europe for six weeks, is organizing a Merchant Marine Hospital Service to afford medical service to foreign merchant seamen in New York and other ports.

New Woman's Hospital.—The new hospital which the trustees of the New York Medical College and Hospital for Women are erecting as an addition to the present building will probably not be completed before the first of next year. The building will cost $45,000, and all but $6,000 of this had been secured before the new hospital was begun. At present over $3,000 more has been collected. The new addition will contain eighty rooms, besides a large operating theater and other necessary offices.

New York School of Clinical Medicine.—A course of clinical lectures with demonstrations will be given at the New York School of Clinical Medicine, 328 West 42d St., on Tuesday evening, commencing October 22. Members of the medical profession are cordially invited. The following subjects will be considered in the autumn course: October 22,—"Various types of chronic endometritis and their treatment," by Dr. Augustin H. Goelet; October 29,—"Scalp wounds and cranial fractures," by Dr. Thomas H. Manley; November 5,—"Some new studies on delirium tremens and alcoholic toxemia, illustrated," by Dr. Thomas D. Crothers; November 12,—"The operative treatment of traumatic and pathological lesions of the joints," by Dr. Robert H. Cowan; November 19,—"Diseases of the naso-pharynx and their treatment," by Dr. Max J. Schwerd; November 26,—"Diseases of the testes and their investments," by Dr. Carl E. Pfister; December 3,—"How to measure, fit and adjust the corset for movable kidney," by Dr. A. E. Gallant; December 10,—"Treatment of chronic gastric catarrh," by Dr. Heinrich Stern, and December 17,—"Trachoma —granulated lids—and its treatment," by Dr. J. Albert Meek.

OHIO.

Cornerstone Laid.—The cornerstone of the addition to St. Elizabeth's Hospital, Dayton, was laid with appropriate ceremonies, October 4.

Isolation Hospital.—The new smallpox hospital at Cleveland, two stories high and with four wards accommodating 80 patients and 8 private rooms, is ready.

Hospital Ward Donated.—Miss Sadie Tod, Youngstown, has notified the trustees of the City Hospital, Warren, that she will donate and equip a ward in the new hospital.

Fountain Park Sanatorium.—Drs. George W. Pickering and Robert Henderson, Urbana, have taken charge of the large hotel buiidiiig at Fountain Park and will convert it into a sanatorium.

Dr. George W. Crile, Cleveland, has been awarded the Alvarenga Prize for 1901, for his essay entitled "An Experimental and Clinical Research into Certain Problems Relating to Surgical Operations."

Dr. Albert P. Ohlmacher, who recently left Gallipolis for Chicago, has been appointed non-resident director of the pathological laboratory of the Ohio Hospital for Epileptics, Gallipolis, and Dr. Theodore L. Chadbourne, at present assistant physician, was promoted to the position of resident pathologist.

Cleveland City Bacteriologist.—Dr. George C. Ashmun, Cleveland, has introduced an ordinance in the city council providing for the appointment of a city bacteriologist at a salary of $1500 per year, who shall work in conjunction with the health office, and who shall furnish trustworthy information respecting the purity and impurity of air, water, and all food substances, and for the prompt detection and prevention of dangerous infectious diseases.

Communicable Diseases.—Diphtheria is reported at Findlay, Cambridge and Zanesville.——Dresden, McConnelsville, Marietta and Cumberland have quarantined against Zanesville on account of the disease.——Smallpox has appeared at Newark, Zanesville and Chatham, and 12 cases are reported at Clay Lick.——Scarlet fever is increasing in Columbus, and the schools of Amanda have been closed on account of the prevalence of the disease at that place.

Personal.—Dr. Peyton E. Cromer, Piqua, has moved to Emporia, Kan.——Dr. Harry B. Kurtz, Leetonia, has located in Elkhart, Ind.——Dr. Yost, Lorain, has decided to locate in St. Paul, Minn.——Dr. Starling S. Wilcox, acting assistant surgeon, U. S. Army, has resigned and resumed practice in Columbus.——Dr. and Mrs. Thomas M. Sabin, Warren, have returned from a trip to Las Vegas, N. M.——Dr. P. R. Bennett, Urbana, has moved to Daytona, Fla.——Dr. William M. Lottridge, Portsmouth, intends to move to Newport, Ky.——Dr. S. D. Good, Newton Falls, has disposed of his practice and will take post-graduate work in New York and Chicago.——Dr. John R. Pipes, Cleveland, has located in Urbana.——Dr. George N. Simpson, Warren, has opened an office in Youngstown.

Fire at Gallipolis Hospital.—During the night of October 15, the pathological laboratory of the Ohio Hospital for Epileptics, Gallipolis, was totally destroyed by fire of unknown origin. Along with the destruction of a splendid equipment for pathologic research a more deplorable loss was sustained in the material which had been accumulated for four years by Dr. A. P. Ohlmacher, director of the laboratory, a material obtained from 176 thorough postmortem examinations of epileptics and including this number of epileptic brains, representing most if not all the phases of the morbid anatomy of the disease. These brains were all properly preserved and in good condition for future study, and numbered among them a remarkable series representing various types of epileptic idiocy and infantile cerebral paralysis. It is no exaggeration to say that this was the most complete and valuable collection of its kind in America. Dr. Ohlmacher's private collection of specimens of embryology, pathology and comparative anatomy was also destroyed.

Cincinnati.

The Laura Memorial Woman's Medical College has opened with a large initial enrolment of students.

St. Mary's Hospital.—At the October meeting of the staff of St. Mary's Hospital, Dr. Thomas Hays was elected to fill the vacancy occasioned by the death of Dr. T. P. White; Dr. H. Freudenberger was elected to the position of pathologist.

Higher Requirements.—The new state medical law requiring students of medicine to have an academic education before matriculating at the local colleges is causing a falling off in the sale of tickets for the clinics at the City Hospital. Heretofore about 250 tickets were sold annually, but this year only 166 have been taken out to date.

Personal.—Dr. Henry W. Bettman has been elected trustee to the Cincinnati Public Library in place of the late Dr. T. P. White.——Dr. Byron Stanton has been elected president of the State Board of Health, vice Dr. W. T. Gemmill, Forest, retired.——Dr. Daniel S. Young, one of the oldest and most esteemed local practitioners, is critically ill with pneumonia at the City Hospital.

PENNSYLVANIA.

West Penn Medical College, Pittsburg, opened for the year, October 2, with an unusually large attendance.

York Hospital.—The trustees of York Hospital are endeavoring to secure for the institution $4500 provided for in the act of assembly of 1874.

Reading Hospital Election.—On October 12, the managers of the Reading Hospital elected William B. Smith, president; Charles Rick, vice-president; Dr. Israel Cleaver, secretary, and P. R. Stetson, treasurer.

Epidemic Disease.—Diphtheria at Forestville has 12 cases.——Verona reports a dozen cases of typhoid and a large number of cases of diphtheria.——The schools of East Berlin, closed on account of diphtheria, have reopened.——Johnstown has 44 cases of scarlet fever, with 6 deaths.

Personal.—Dr. Benjamin H. Detwiler, Williamsport, was given a banquet by the profession of Williamsport and its vicinity, October 7, in honor of his seventieth birthday anniversary.——Dr. Levi F. Wagner, Pikesville, has moved to Reading.——Dr. Frederick E. Jenkins, Carbondale, has returned from the Philippines and is stationed at Fort Morgan, near Mobile, Ala.—Dr. Isaac Ohlman, Meadville, has decided to locate in Pittsburg.——Dr. John L. Wright, physician for the Pennsylvania Relief Association at Erie, has been transferred to Pittsburg.

Philadelphia.

Five Philadelphia hospitals receive $5000 each by the will of the late Thomas Elkinton of Philadelphia.

Smallpox.—This year there have been 287 cases of smallpox, with 36 deaths. Sixty new cases were reported during the last week and the municipal hospital now has more than 150 patients.

Personal.—Dr. S. Ashton Bonnaffon, of the Pennsylvania Relief Association, has been transferred to Erie.——Dr. Samuel McCullagh has resigned as resident physician of Girard College, and Dr. Henry G. Godfrey has been elected his successor.

Wills Hospital Changes.—Dr. William F. Norris has resigned after thirty years' service, as attending surgeon. Dr. John N. Kirk has been appointed resident physician, Dr. Paul J. Pontius, assistant surgeon, and Dr. George C. Harlan, consulting surgeon. Dr. William Zentmayer has been appointed attending surgeon, vice Dr. Norris, resigned.

CANADA.

G. M. McMicking, M.D., McGill, 1849, died, October 13, at his home in Toronto, aged 76. He practiced in Chippewa until 1867, and afterwards in Goderich for twenty-two years. He was a member of the legislature for twenty-two years.

Protestant Hospital for the Insane at Quebec.—The quarterly report of this hospital shows that 40 patients were admitted during that time, and that 13 had been discharged therefrom; 10 deaths occurred. The number at present undergoing treatment in this institution is 403.

Typhoid Among Troops.—Several of the officers and men of the Duke of York's Hussars, at Montreal, are suffering from attacks of typhoid fever. It is thought that the infection occurred at Quebec City, where the corps was participating in the arrival of the Duke and Duchess of Cornwall and York.

Canadian Nurses' Association.—The annual meeting of this Association was held in Montreal, on Tuesday evening, the 15th inst., Miss Rogers, the President, in the chair. The number of registrations reached 1034. During the present year the Association was incorporated by provincial charter.

Hotel Dieu Hospital, Montreal.—Hotel Dieu, the oldest hospital in the City of Montreal, has decided to establish a training school for nurses, so that hereafter French-Canadians and Catholics will not be dependent upon English institutions for trained nurses. The public will be appealed to for assistance in the project.

Personal.—Dr. Harry W. Spence, of Toronto, who has been taking a post-graduate course in England, has been successful in obtaining the degrees L.R.C.P. London, and M.R.C.S. England, and has been appointed surgeon on the steamer *Mombasa,* one of the British India Steamship Company's passenger steamers from London to Calcutta.

Montreal General Hospital.—The governors of this institution have declined an offer of $25,000 for twenty thousand feet of land adjoining the present site of the General Hospital. Dr. J. B. McConnell presented the report of the management committee. The receipts from May 15 to October 9, amounted to $5015, and the expenditure $5719. The debt remains about the same as at the annual meeting, viz., $7948.

School Children and Vaccination.—The officials of the Health Department of Montreal are making special efforts to ascertain if pupils attending the public schools are being properly vaccinated, owing to the appearance once more in that city of the dread disease, and also on account of there being so many cases of smallpox in the province. As vaccination is not compulsory in the Province of Quebec, an effort will be made when the legislature meets to make it so.

Conference on Smallpox.—Dr. P. H. Bryce, secretary of the Ontario Board of Health, and Dr. Pelletier, secretary of the Quebec Board of Health, held a conference with the local board of health, at Ottawa, on the 14th inst., with regard to the epidemic of smallpox in that city. It is a noteworthy fact that out of the first twenty-four cases of smallpox reported, but one had previously been vaccinated. There have been thirty-four cases in all; the outbreak is now well under control.

Failure of the Physicians' and Surgeons' Supply Company.—Some months ago mention was made in these columns of the formation in Ontario of a supply company of the above description for practitioners in this province. It was thought at the time the association was organized that physicians were not receiving fair treatment at the hands of the drug trade. The organization was perfected in November last; the company began business in March of the present year. A directorate of physicians controlled the affairs of the company, which is now being wound up.

Medical Graduates and the Army.—Cable dispatches record that a Canadian medical graduate has been refused permission to serve on the British Medical Staff in South Africa; and the action of the home authorities in this connection is raising in the minds of military surgeons the question: What has become of the promised imperial legislation to permit duly qualified and certificated graduates of colonial medical colleges to enter the imperial service? Some months ago the Militia Department at Ottawa was notified that an act of this character had been introduced into the imperial parliament, but since that time nothing more has been heard of the matter; and it is not known whether the promised legislation passed into law or was thought to be a too generous concession to colonial medical graduates.

FOREIGN.

Plague at Rio Janeiro.—Two new cases of bubonic plague were found October 19, and three on the 20th, making 52 cases at the present time in the hospital.

Physician Contracts Leprosy.—Dr. Feilberg, city physician of Copenhagen, has contracted anesthetic leprosy. He had recently visited the West Indies.

Leper Hospital in Iceland.—The Order of Odd Fellows in Denmark established the Laugarnoes Hospital for lepers, October, 1898. At the end of 1899, 81 patients had been received, of which 18 are dead, and 2 have been discharged as cured.

The International Congress for Obstetrics and Gynecology will be held in Italy in 1902. The Russians have made great efforts to secure the congress in honor of the completion of the Academy for Obstetrics and Gynecology at St. Petersburg, the only institution of its kind in the world, our foreign exchanges assert. It has been erected under Ott's supervision by funds supplied by the Czar. The congress committee, however, had already made arrangements for the meeting in Italy. The first congress was held in Brussels, the second in Geneva and the third in Amsterdam.

International Congress of Tropical Diseases.—The Egyptian Medical Congress announced to convene at Cairo in December, 1902, will be practically a congress of tropical diseases, and the committee in charge would be glad to enlarge its scope and announce it as an international congress for this purpose. The realization of this project, however, they know depends on the co-operation of those interested in epidemiology and tropical pathology the world over, and they scarcely venture to hope for this. The list of communications already announced includes studies of the diseases, etc., prevalent in Egypt and Ethiopia, divided into three sections, medicine, surgery and ophthalmology.

PARIS LETTER.

President McKinley's death has been the cause of various comments on the part of the medical and political press in France. There has been quite a diversity of opinion shown, and it would seem as if the political newspapers had tried to cast doubts upon the manner in which the treatment was carried out. Certain medical men, hiding behind a pseudonym, and signing themselves with an X., have given forth views which showed their lack of appreciation of the difficulties to be encountered in the treatment of so desperate an injury. On the other hand, in the medical papers of good standing, the quickness with which a decision was come to has been much praised, and it has been repeatedly said that nowhere but in America such ready adaptability to the requirements of the time could have been found. There was, however, one fact, which impressed all medical men having some knowledge of the course observed in penetrating wounds of the abdomen, and that was the highly optimistic tendency of the bulletins issued.

Rabies.

The last statistics of the Pasteur Institute show how beneficial the treatment of rabies by inoculation has become. According to Tardieu, Thamhayn and Bouley, out of 855 cases of people bitten by mad dogs and who were not treated, death took place in 46,6 per cent. of the cases. The physicians of Alfort, Toulouse, Lyons and Berlin consider that about a third of the patients bitten by animals suffering from rabies are affected later with hydrophobia. On the other hand, in 1886, the first year the new treatment was tried, 2671 patients were inoculated at the Pasteur Institute and only 25 died, which makes a percentage of 0.94 per cent. In the last three years, 1898, 1899, 1900, 4499 persons were treated by this method and only 11 died, which makes the very low record of 0.25 per cent. Roux and Nocard's researches have shown that if, after three or four days, the dog suspected of rabies has shown no specific symptoms, the person who has been bitten is running no danger of infection. The disease itself runs a course of 10 days, so this is a means of making the diagnosis.

Epidemic of Smallpox.

Dr. Roger, physician of the Aubervilliers smallpox hospital, has just published the statistics of the cases of smallpox in Paris during the first six months of the year. There were in all 1996 cases with 274 deaths. There were over a hundred cases in the 20th and 23d week. Certain parts of Paris have been singularly free from the epidemic, such as the Champs-Elysées quarter where there were only 23 cases. The neighborhood of hospitals seems to be particularly disadvantageous, the two quarters around the Aubervilliers and the Pasteur Hospital having the greatest number of cases, 258 and 360. The mortality in Dr. Roger's service is 24 per cent., which is rather large. There seems to be at present a smaller number of cases, but Dr. Roger does not consider that the epidemic is over and he recommends vaccination every three years, as numerous facts collected during the recent epidemic show that the immunity is of much shorter duration than was at first imagined.

Congress of Gynecology and Obstetrics.

At the recent Congress of Gynecology and Obstetrics held at Nantes, Dr. Baudron of Paris spoke of the method he used, which consists in simple dilatation, in cases of uterine anteflexion with dysmenorrhea and sterility. He compared it to the other methods used, such as hysterotomy or ventrofixation.

Dr. Varnier made a report on the treatment of uterine rupture and described the results obtained by the old methods, such as extraction of the child and tamponing, and others obtained of recent date by laparotomy. The latter are much better and Dr. Varnier said that it was hard to decide after manual examination per vaginam, if rupture was complete or incomplete. The best course to follow was immediate laparotomy. Professor Pinaud insisted on the dangers of uterine rupture; some cases did not seem at first so alarming. He advocated immediate laparotomy in all cases. Dr. Pinaud also spoke on the use of aniodol as an antiseptic. He has been using it extensively in his service at the Clinique Baudelocque, and has found that it can be used in washing the eyes of the newborn infants.

Artificial Horse Bites.—A French exchange states that a new means of defrauding the public has recently been discovered in Paris. An instrument was made which produced a wound resembling the bite of a horse and damages were claimed from the owner of the horse incriminated as the assailant.

Correspondence.

Regarding Propagation.

CHICAGO, Oct. 8, 1901.

To the Editor:—In the discussion of Dr. George J. Englemann's interesting paper on the "Increasing Sterility of American Women," reported in THE JOURNAL for October 5, there are exhibited a depth of concern and a degree of alarm that do not seem to be warranted by those disclosures in the Doctor's paper which furnished the material for the greater part of the discussion.

The chief facts shown in the paper are, that sterility has increased rapidly during the last century; that the present average percentage of childless marriages in this country is about twenty; that the average number of children per married couple is 1.8, and that the chief causes of this increasing sterility and diminishing fecundity are the intentional prevention of conception and interruption of gestation.

These are intensely interesting facts, and the labor which their accumulation must have cost the author, entitles him to the highest praise. It may also be conceded without argument that the condemnation which the professional abortionist, the advertiser of abortifacients, and the male distributers of Neisser's diplococci, received at the hands of those who discussed the paper, was entirely just. But the mere facts that 20 per cent. of American marriages are childless, and that the number of children per married couple is only 1.8, do not seem to warrant the alarm that was exhibited in their discussion.

If these facts forebode a danger that constitutes sufficient grounds for alarm, this danger must be one which menaces either ourselves and our actual descendants, or those potential individuals of the future whose actual existence is prevented by our increasing infecundity. There can be no danger that threatens any one else.

What danger is there in these facts for us or our descendants? Would the struggle for existence be easier, or the joy of living greater, if there were more people in America or in the world? Is there any profession, trade, or calling that is not already enormously overcrowded? If we need more tillers of the soil, why has the exodus from the country to the town gone so swiftly forward that 47.1 per cent. of our present population is in incorporated towns and cities? If there is, on the other hand, a village, town, or city in America that needs more people than it has, why is it necessary for so great a part of the existing urban population to live in tenements (which, by courtesy, are called flats), and support families on $6.00 a week? Every new child born into the world is a prospective competitor of those already here. It must elbow its unwelcome way into an already overcrowded world, in which it will find no nook or corner fit to live in that is not already occupied, and no vocation from whose representatives it will receive a welcome. Let us be frank and admit that, for us and our descendants, there is encouragement rather than peril in the alleged diminution of our rate of increase.

Taking the other horn of the dilemma, we shall find it equally ridiculous to talk of doing missionary work in the interests of possible children that have never even begun to be. It is here assumed that a child "begins to be" at the moment of conception.

According to Henle's estimate, every woman produces 72,000 ova, each one of which is susceptible of fecundation and capable of development into a mature human being. Every one of these ova that fails to become fecundated becomes a dead human possibility. Should we endeavor to bring about the fecundation of all? If not of all, who shall decide how many?

Let us again be frank and admit that, until we shall have ameliorated the condition of the actually existent, we need not concern ourselves with the fate of these shadowy hosts of the merely potentially existent. We may go still further and insist that it is not necessary to countenance abortion, to be able to say that a marriage which is comparatively barren of children, may still be prolific of happiness, and that to make the propagation of the species the sole aim of marriage, is to degrade that institution to the spiritual level of a breeding farm.

Indeed, in normal cases, it is questionable whether the definite desire for children ever is a motive to marry. Love of the consort certainly long precedes the desire for children, and is a sufficient inducement to insure the perpetuation of the race. Desire for children comes later; for Nature has a way of accomplishing her mysterious purposes by appearing to let us do what pleases us, and then pleasing us with what she has enticed us into doing against our wishes.

A. C. MCCLANAHAN, M.D.

Book Notices.

INTRODUCTION TO THE DIFFERENTIAL DIAGNOSIS OF THE SEPARATE FORMS OF GALLSTONE DISEASE, Based upon his own Experience Gained in 433 Laparotomies for Gallstones. By Professor Hans Kehr, Halberstadt. Authorized Translation by William Wotkyns Seymour, A.B. Yale, M.D. Harvard. Formerly Professor of Gynecology in the University of Vermont. With an introduction by Prof. Kehr. Cloth. Pp. 370. Price, $2.50. Philadelphia: P. Blakiston's Sons & Co. 1901.

The literature of gallstone surgery in our language of late years has become quite considerable. Nevertheless, the addition of this translation from a leading German work on the subject will be of value to American readers. There is no question as to the importance of the subject and if the operative treatment of these conditions has not become so extensive in this country as it has in Germany, as hinted in the preface, the book will doubtless serve to bring about this desirable result. Professor Kehr has himself added a preface to this American edition in which he gives his views as revised from his latest experiences. In the selection of operative methods he employs cystectomy with drainage in this condition more and more. In this way he says we avoid more certainly true and false recurrences. Professor Seymour has given us an intelligent translation, but it contains a great many German constructions and can not be said to be quite as elegant English as it might be. Still, it is hard for a person who reads German much or little to avoid such slips occasionally in the translation of a language so difficult as German.

THE ESTIVO-AUTUMNAL (Remittent) MALARIAL FEVERS. By Charles F. Craig, M.D. (Yale), Acting Assistant-Surgeon, U. S. A. Illustrated by 2 Colored Plates and 21 Clinical Charts. Cloth. Pp. 221. Price, $2.50. New York: William Wood & Co. 1901.

The author has given us in detail a description of certain fevers too little understood by the great mass of the profession. The opportunity presented to him while he was connected with military hospitals at home as well as in Cuba and the Philippines, was well utilized in a systematic and scientific study of the malarial diseases in their protean aspects, the result of which is published in this volume. He gives us an account of the estivo-autumnal parasites, describes them, giving their natural history, or life cycle within the mosquito, their varieties, method of staining, examination, etc. The etiology, pathology, diagnosis, prognosis, treatment, methods of infection, etc., of malaria are fully considered. The book is a most interesting addition to the literature on the subject and will be found invaluable to those who are desirous of understanding and thoroughly mastering the facts in regard to malaria. The manner in which the author has presented the subject is commendable in that it is simple yet scientific.

MANUAL OF THE DISEASES OF CHILDREN. By John Madison Taylor, A.M., M.D., Professor of Diseases of Children, Philadelphia Polyclinic, and William H. Wells, M.D., Adjunct Professor of Obstetrics and Diseases of Infancy in the Philadelphia Polyclinic. Second Edition, Thoroughly Revised and Enlarged. Illustrated. Cloth. Pp. 859. Price, $4.50. Philadelphia: P. Blakiston's Son & Co. 1901.

The authors have thoroughly rewritten their work, adding a number of new chapters and special articles. One of the points

in which it will be found up to date is that of infant feeding, and still other matters are also well brought up. Much new matter has been added to the portions on diseases of the nervous system and respiratory disorders. A chapter on ear diseases, which is a very important matter in children, has been added.

Deaths and Obituaries.

J. G. Kerr, M.D., Jefferson Medical College, Philadelphia, 1847, who was one of the best known medical missionaries in China, died at his home in Canton, China, aged 77. He was born in Adams County, Ohio, and for a time practiced in this country, but the past forty-five years he had devoted to his work among the Chinese. He was eminent as an operator for urinary calculi, and in 1898 was called to operate upon the American Minister to China. During the last few years he established and superintended an asylum for the insane, something previously unknown in that country. He also accomplished much in his translations of medical works into Chinese for the use of the students.

Philip Goode Gillett, M.D., for many years superintendent of the Illinois Institution for the Education of Deaf Mutes, died at his home in Jacksonville, Ill., October 2, aged 67. He was connected with the above institution in a minor capacity during his student days and became interested in deaf mute work and devoted all his energies in that direction. He was the first to introduce instruction in articulation and lip reading in a state institution, and he brought about the establishment of the Illinois State Board of Charities.

George W. Burke, M.D., Jefferson Medical College, Philadelphia, 1866, died at his home in New Castle, Ind., October 18, from Bright's disease, aged 59. During the Civil war he was an assistant surgeon in the 46th Pennsylvania and later in the 20th Army Corps, serving until the close of the war. He practiced for a time at Sulphur Springs, Ind., but for the past thirty-five years had practiced at New Castle. He was a member of the American Medical Association.

Charles H. Brown, M.D., University of the City of New York, 1879, died at his home in New York City, October 15, aged 45. He was for many years the managing editor of *The Journal of Nervous and Mental Diseases* and was connected with the New York Dispensary, the Post-Graduate and the Presbyterian hospitals, and the outdoor work of Bellevue Hospital.

Donald R. Hinckley, M.D., Harvard Medical School, Boston, 1896, shot and killed himself, probably accidentally, while visiting his parents at Northampton, Mass., October 14. He was a graduate of Yale University in the class of '92, and had been in active practice at New Haven, Conn., having recently been appointed instructor in the Yale Medical School. He was aged 31.

Joseph H. Wythe, M.D., Philadelphia College of Medicine and Surgery, 1850, died at his home in Oakland, Cal., October 14, after a long illness, aged 79. He was born in Manchester, England, and during the Civil war was assistant surgeon. He remained in the army for a number of years after the close of the war, and, after resigning his commission, studied for the ministry.

Robert Henry Nesbitt, M.D., College of Physicians and Surgeons, New York, 1899, died, October 10, at the New York Hospital of which he was once an interne. He had just returned from Europe when he was seized with his fatal illness, a strangulation of the intestine. His home was at Wheeling, W. Va.

Hiram P. Tuttle, M.D., University of California, 1869, died at Tacoma, Wash., October 9. He retired in 1898 in order to devote his entire time to the perfection of thorite, a high explosive, for the purchase of which Congress had made an appropriation at its last session.

Horace Bigelow, M.D., College of Physicians and Surgeons, New York, 1896, died in Roosevelt Hospital, October 15, from typhoid pneumonia, aged 28. He was born in Fayetteville, N. Y., and at the time of his death was a member of the outdoor staff of the hospital named.

Henry Raymond Rogers, M.D., Jefferson Medical College, Philadelphia, 1851, died at his home in Dunkirk, N. Y., October 19, aged 79. He retired from practice several years ago for scientific and literary work. As a writer he was noted for his original views.

Porter W. Felt, M.D., Detroit College of Medicine, 1882, died at his home in Belleville, Mich., where he had practiced for the past twenty years, October 12, from the result of an overdose of morphin, taken, it is believed, by accident. He was aged 44.

William W. Duval, M.D., University of Maryland, Baltimore, 1843, died at his residence, Gladswood, Prince George County, Md., October 13, aged 80. He was president of the county school board and identified for forty years with public education.

Hannah E. Longshore, M.D., Woman's Medical College, Pennsylvania, 1851, died in Philadelphia, October 18, aged 82. She was the first woman to practice medicine in the city named and served as a demonstrator of anatomy.

William G. Fisher, M.D., Medical Department Washington University, St. Louis, 1866, died at his home in Marshall, Mo., October 9, aged 57. He practiced for a number of years at Napton, Mo., moving to Marshall in 1896.

Herbert J. Hale, M.D., Detroit Medical College, 1875, died at his home in Grass Lake, Mich., October 3. At its recent meeting the Jackson County (Mich.) Medical Society passed resolutions of respect for his memory.

John Semple, M.D., Jefferson Medical College, Philadelphia, 1848, died at his home in Wilkinsburg, Pa., October 9, after an illness of two weeks, aged 80. He was burgess of Wilkinsburg from 1888 to 1890.

Frederick Loeber, M.D., New Orleans School of Medicine, 1866, died at his home in New Orleans, October 18, aged 63. He was for thirty-one years the head of the Touro Infirmary and was a prominent physician.

Samuel Edward Stiles, M.D., Long Island College Hospital, New York, 1870, died in Brooklyn, N. Y., October 9, aged 67. He was a noted genealogist and retired from active practice some years ago.

Wesley A. Vineyard, M.D., Tennessee Medical College, Knoxville, 1890, died at his home in Luttrell, Tenn., October 9, from heart failure, aged 41. He was a representative to the Legislature in 1900.

Edwin T. Edgerton, M.D., Pennsylvania Medical College, Philadelphia, 1851, died at his home in Saline, La., October 14, from the effects of a cancer, aged 75. He was a native of South Carolina.

Chester L. Gross, M.D., Jefferson Medical College, Philadelphia, 1861, died suddenly at his home in Pen Argyl, Pa., October 9, aged 65. He formerly practiced at Freemansburg.

Ernest Schottky, M.D., College of Physicians and Surgeons, New York, died at his home in Passaic, N. J., October 18, aged 56. He at one time resided in New York City.

William L. Harding, M.D., New York University, 1860, died at his home in New York City, October 11. He was a surgeon in the Union army during the Civil war.

Charles W. Lawrence, Jr., M.D., University of Tulane, New Orleans, 1900, died at his home in Longview, Texas, from typhoid fever, October 4.

J. H. Tabler, M.D., University of Tennessee, Nashville, 1892, died at his home in Lawrenceburg, Tenn., October 13, after a brief illness.

Jefferson M. Mason, M.D., University of Arkansas, Little Rock, 1888, died at his in Floresville, Texas, October 12, after a long illness.

W. A. Withers, M.D., Rush Medical College, Chicago, 1898, died at his home in New Orleans, October 14, after a long illness.

Societies.

COMING MEETINGS.

Medical Society of Virginia, Lynchburg, Nov. 5-7, 1901.

Oklahoma Territory Medical Association, Oklahoma City, Nov. 13, 1901.

Southern Surgical and Gynecological Association, Richmond, Va., Nov. 12-14, 1901.

Western Surgical and Gynecological Association, Chicago, Dec. 18-19, 1901.

Southern California Medical Society will meet at Los Angeles, December 4 and 5.

Central Medical Association.—At a meeting of this Association, held at Middletown, Conn., October 7, it was voted to retain the same officers for the coming year.

Holyoke (Mass.) Medical Society.—This Society met October 7 and elected Dr. C. A. Allen, president, Dr. D. F. Donoghue, vice-president, and Dr. J. J. McCabe, secretary-treasurer.

Inland Empire Clinical Society.—This Society was recently recognized by and affiliated with the Idaho State Society, thus giving the former the full privileges of a country or district medical association.

Guthrie (Okla.) Medical Society.—At a meeting of this Society, October 7, the following officers were elected: Dr. R. V. Smith, president; Dr. J. L. Melvin, vice-president, and Dr. E. O. Barker, secretary-treasurer.

Idaho State Medical Society.—The ninth annual meeting of this Society was held at Pocatello, October 3 and 4, and Dr. Hubert A. Castle, Pocatello, was elected president, and Dr. Ed. E. Maxey, Caldwell, re-elected secretary-treasurer.

Southern Manitoba Medical Society.—This Society was organized at Napinka, October 9, and the following officers elected: President, Dr. E. J. McConnell, Morden; vice-president, Dr. Frederick L. Schaffner, Boissevan, and secretary-treasurer, Dr. T. J. Lamont, Treherne.

Detroit (Mich.) Academy of Medicine.—The regular meeting of this Academy was held, October 8, and Dr. Arthur D. Holmes was re-elected to the presidency; other officers elected were Dr. Wadsworth Warren, vice-president, and Dr. Harrison D. Jenks, secretary-treasurer.

McKean County (Pa.) Medical Society.—At the meeting of this Society held in Bradford, October 8, the officers elected were as follows: Dr. William P. Burdick, Mt. Jewett, president; Dr. James C. Walker, Bradford, vice-president, and Dr. B. H. Hall, Bradford, secretary-treasurer.

Stafford District (N. H.) Medical Society.—The ninety-fourth annual meeting of this Society was held at Dover, October 9, and the following officers elected: President, Dr. William H. Nute, Exeter; secretary, Dr. Lewis W. Flanders, Dover, and treasurer, Dr. John R. Ham, Dover.

White County (Ill.) Medical Association.—At the regular meeting of this Association, at Grayville, October 15, the following officers were elected: President, Dr. V. H. Parker, Grayville; vice-presidents, Drs. J. N. Hopkins, Burnt Prairie, and I. A. Foster, Herald; secretary-treasurer, Dr. W. A. Steele.

Fergus County (Mont.) Medical Association.—This Association was recently permanently organized with the following officers: President, Dr. J. B. Atchison, Lewiston; vice-president, Dr. W. A. Long, Lewiston; secretary, Dr. Frederick Treacy, Lewiston, and treasurer, Dr. C. A. Tillotson, Gilt Edge.

Jackson County (Mo.) Medical Society.—At the meeting of this Society, held in Kansas City, October 10, the following officers were elected: President, Dr. William Frick; vice-president, Dr. Walter S. Wheeler; secretary, Dr. Edward H. Thrailkill, and treasurer, Dr. Louis W. Luscher, all of Kansas City.

El Paso County (Texas) Medical Society.—At the third annual meeting of this Society, at El Paso, October 12, the following officers were elected: President, Dr. S. T. Turner; vice-president, Dr. W. N. Vilas; secretary, Dr. J. A. Rawlings (re-elected), and treasurer, Dr. H. E. Stevenson (re-elected), all of El Paso.

Corsicana (Texas) District Medical Association.—At the regular meeting of this Association, October 8, the following officers were elected: President, Dr. T. A. Miller; vice-presidents, Drs. T. L. Slater, Re, and M. L. Langford, Corsicana; secretary, Dr. W. D. Fountain, and treasurer, Dr. L. E. Retton, both of Corsicana.

Tennessee Valley Medical Association.—This Association met at Athens, Ala., October 8 and 9, and elected the following officers: President, Dr. Felix E. Baldridge, Huntsville; vice-presidents, Drs. F. P. Pettey, New Decatur, and T. E. Casey, Albertsville; secretary, Dr. Thomas E. Dryer, Huntsville, and treasurer, Dr. Edgar Rand, Huntsville.

Cedar Falls (Iowa) Medical Society.—The annual meeting of this Society was held at Cedar Falls, October 8 and 9, and the following officers were elected: President, Dr. George B. Thompson, Winthrop; vice-president, D. M. Wick, Cedar Falls; secretary, Dr. T. U. McManus, Waterloo, and treasurer, Dr. R. E. Buchanan. The next meeting will be held in Waverly.

Jefferson County (Tenn.) Medical Society.—The physicians of this county met October 8 and reorganized this Society, which has been dormant for the past twenty years. The following officers were elected: Dr. I. M. Tittsworth, Jefferson City, president; Dr. C. L. Cline, White Pine, vice-president; Dr. S. W. Fain, secretary, and Dr. P. A. Tinsley, Dandridge, treasurer.

Medical Association of Northern New York.—At the meeting of this Association held at Plattsburg, October 8, the following officers were elected: President, Dr. Frank Madden, Plattsburg; vice-president, Dr. Walter S. Daly, Ogdensburg; treasurer, Dr. George H. Oliver Dickinson, and secretary, Dr. Alfred G. Wilding, Malone. Dr. Cassius D. Silver, Plattsburg, was elected delegate to the State Medical Association.

Albany County (N. Y.) Medical Association.—The members of the Second District Branch residing in Albany County met, October 9, and organized this Association, electing the following officers: President, Dr. Charles M. Culver, Albany; vice-president, Dr. Adam T. Van Vraken, Watervliet; secretary-treasurer, Dr. William B. Sabin, Watervliet; fellow, Dr. W. R. Lothridge, Verdoy, and alternate, Dr. John U. Haynes, Cohoes.

Tri-State Medical Society.—This Society, representing the states of Alabama, Georgia and Tennessee, met at Nashville, October 8, 9 and 10, and the following officers were elected: President, Dr. John C. LeGrand, Birmingham; vice-presidents, Drs. Pugh U. Brown, Troy, Ala., William P. Harbin, Rome, Ga., and James C. Wilson, Rockwood, Tenn.; secretary, Dr. Frank T. Smith, and treasurer, Dr. George R. West, both of Chattanooga. The next place of meeting is Birmingham, Ala.

San Joaquin Valley Medical Association.—At the annual meeting of this Association, held in Stockton, Cal., October 8, the following officers were elected: President, Dr. Henry Hildreth, Delano; vice-presidents, Drs. B. F. Surrhayne, Modesto, J. L. Carson, Bakersfield, and J. B. Rosson, Tulare; secretary, Dr. W. S. Fowler, Bakersfield; assistant secretary, Dr. D. B. Trowbridge, Fresno, and treasurer, Dr. T. M. Hayden, Fresno. The next meeting will be held in Fresno, the second Tuesday in March, 1902.

Wyoming State Medical Society.—The fifth annual meeting of this Society was held at Evanston, October 8 and 9, and the following officers were elected: President, Dr. G. G. Verbryck, Cambria; vice-presidents, Drs. F. H. Harrison, Evanston, W. C. Burk, Rock Springs, and W. A. Wyman, Cheyenne; secretary, Dr. C. H. Solier, Evanston; treasurer, Dr. J. L. Wicks, Evanston; delegate to the American Medical Association, Dr. R. Harvey Reed, Rock Springs; alternate, Dr. E. E. Lewis, Spring Valley. The next place of meeting was fixed for Cheyenne in joint session with the Rocky Mountain Interstate Medical Association.

Vermont State Medical Association.—The eighty-eighth annual meeting of this Association was held in Montpelier, October 10 and 11, and it was voted unanimously to reorganize on a basis of the county medical societies, that is, to establish in each county a society in affiliation with the State Association; a committee of three, consisting of Drs. D. C. Hawley, Burlington, J. M. Hamilton, Rutland, and W. D. Huntington, Rochester, was appointed to complete the organization throughout the state, and were empowered to employ one of their own number or any other member in good standing as organizer to visit the various counties. The following officers were elected for the coming year: President, Dr. J. B. Wheeler,

Burlington; vice-president, Dr. M. F. McGuire, Montpelier; secretary, Dr. G. H. Gorham, Bellows Falls, and treasurer, Dr. J. W. Avery, Proctor. Burlington was selected as the next place of meeting.

CINCINNATI ACADEMY OF MEDICINE.

Regular Meeting, Oct. 7, 1901.

President Dr. N. P. Dandridge in the Chair.

Discussion on Major Wm. O. Owen's Paper. **(See p. 1110.)**

Dr. P. S. Connor (medical member of the commission appointed by President McKinley to investigate the conduct of the Spanish-American War) opened the discussion on Major Wm. O. Owen's paper, "Preventable Disease in the Army of the United States; Cause, Effect and Remedy." He stated that many of the lessons which the Civil war had taught seemed to have been forgotten in the Spanish-American war. It was certainly possible to have prevented many of the diseases, particularly typhoid fever, but unfortunately preventive measures were not instituted in time. He stated that in many instances the seeds of typhoid fever were carried into the camps from the starting points of the troops, and that the soldiers were not infected so much from the camps established later. Then again crowd poisoning was a potent factor in breeding disease. A large part of the medical force was unfamiliar with military matters and camp sanitation. Sinks, in Camp Thomas, for instance, were not dug until ten days after the troops arrived, and when dug were soon allowed to fill up and overflow. Everything that was unsanitary, it seemed, existed at Camp Thomas. And what was true of this camp was true of many others to a greater or less degree. If troops could have been kept in small companies, thoroughly isolated and inspected regularly, nothing like the amount of sickness would have occurred. The morale of the camps was bad, and the country will suffer for many years from the results of the diseases engendered in these camps; pension grants will increase materially from year to year.

The responsibility for disease should be established, but as to how we are to get out of the existing difficulties he did not know. Reform should begin with the Medical Department, and not with a medical officer here and there. Medical officers have not enough authority. Give them authority along the lines of sanitation, inspection of troops, medical supplies, etc., and then hold them responsible for any dereliction of duty along these lines. Nothing in the way of reform can be accomplished unless the movement begins in the Medical Department of the army. Unquestionably the Medical Department should have its own transportation. Many times supplies arrived at their destination but could not be gotten out of the cars without orders; in other instances supplies that were started promptly on their way did not arrive at all. In conclusion, Mr. Connor said that everybody realized the necessity for radical changes in the Army Medical Department, but thought that nothing would ever be accomplished through resolutions passed by different medical societies throughout the country. It was unfortunately true that a word from one of the dozen prominent politicians who could be named would carry more weight and be more liable to accomplish results than the resolutions of all the medical societies of the country. Finally, considering all the circumstances connected with the Spanish-American war, it was wonderful that the Medical Department got along as well as it did, and that there were not more lives sacrificed.

Dr. S. P. Kramer (major and surgeon, U. S. Volunteers, Spanish-American war) stated that sufficient time had not elapsed since the war, for the people to calmly think over the lessons to be learned from experience. Many adverse criticisms had been made of the Medical Department, some of which were no doubt just, but it must be remembered that the causes leading to such criticism were and are just as rife in civil life as in the army. He had listened during the evening to a good deal of criticism of army regulations, but to him army regulations were a necessity, and red-tape an essential part of the system; the regulations of the United States Army were the compilation of the experiences of men who had seen years of service and were therefore fully competent to formulate plans for the guidance of the army. As in civil, so in army life, a great deal depends upon the individual. He himself had had no trouble in obtaining medical supplies, but he knew those who did, and in many such cases the fault was with the medical officer. Some of them wasted supplies; others did not go about obtaining them in the right way. The causation of typhoid fever was due to the unsanitary condition of the camps; the remedy for this was education along the line of sanitation, and if the laws of governing this branch of camp equipment should be violated the offender should be severely punished. He wished to offer the suggestion that many of the so-called laws of sanitary science were by no means thoroughly worked out, and that officers of the line could not be very severely blamed for not following what were to them, at the best, but theories. But he thought that such of the laws of the science as were known should be taught officers of the line at the military academy at West Point. He thought Major Owen was right in bringing this matter before the authorities, and likened him unto a wedge which would be considerably hammered and the edge taken off it, for his temerity in forcing these unwelcome truths upon the army. Contract surgeons, he said, occupied a very anomalous position; they have no responsibility; practically they can resign after giving two weeks' notice; they are exposed to all the risks a regularly appointed medical officer runs; they are not in the line of promotion, and they have not the authority of the regularly appointed medical officer, which is little enough, it is true. Under such disadvantages the service does not get the best there is in these men. In conclusion, Dr. Kramer stated that notwithstanding all the disadvantages under which the army corps labored, the mortality from typhoid fever was but little, if any, greater than that obtained in private practice or in the large public hospitals of civil practice.

Dr. Byron Stanton (late major and surgeon, U. S. Volunteers, 1861-65) said that the paper of Major Owen strongly impressed what has been often said, that it is not the carnage of battle, but the pestilence that lurks in the camps, that is most to be feared. It is a sad commentary on the management of our troops that so large a per cent. of the deaths should have been from typhoid fever, a disease more easily prevented than any other except smallpox. When nearly 22 per cent. of the soldiers, selected, as Dr. Owen has said, from among the flower of young American manhood, suffer from a preventable disease there must be something wrong with those in authority. I am sure that the figures given are not exaggerations. I believe it to be an underestimate, although coming from official sources. The investigations of the commission consisting of Drs. Walter Reed, E. O. Shakespere and Victor C. Vaughan, appointed to study the causes and spread of typhoid fever among the troops at various camps in the United States during the Spanish-American war, show that many of the cases returned under the head of diarrhea, continued fever and malaria, were undoubtedly cases of typhoid fever. The report of Dr. Vaughan, one of the commission, shows that more than 80 per cent. of the deaths from the Spanish-American war were from typhoid fever. That much of the mortality might have been prevented by means known to sanitarians, I fully believe. During the Civil war the per cent. of mortality from the preventable diseases was, no doubt, greater, but at that time much less was known about preventive medicine than was known in 1898 and 1899.

With the advance in sanitary knowledge greater responsibility rests upon those having charge of camps and troops. The application of knowledge now in possession of sanitarians has resulted in a marked diminution in the last decade in the mortality of cities and towns, amounting to 180 in 1,000,000 of population, as shown by the vital statistics published by the U. S. Census Bureau. The application of the same knowledge to camp sanitation would have resulted in a greater saving of life among the soldiers. By means known to sanitarians before the outbreak of the late war, the death-rate should have been greatly lessened. That knowledge was not possessed by other officers though known to and urged upon them by the Medical Corps of the Army, but with the indifference to advice

from medical sources, even in regard to medical matters, that is characteristic of the average commanding officer, the most threatening danger of camp-life—filth—was permitted to exist. Waste was not safely and duly disposed of, consequently there was contamination of water supplies, and the other known means of communicating typhoid fever were present. The spread of typhoid fever is generally attributed to the use of water contaminated by the feces of typhoid patients, and this is, no doubt, the chief cause of its spread, but it is not the only cause. Air-borne typhoid is of more common occurrence than has generally been supposed. This is especially true among soldiers. Other sources of infection than water contaminated with feces, are here more potent than in civil life. The dangers intensified by army life are as follows: Water contamination by the urine of typhoid patients, an undoubted source of danger; contamination of the camp with fecal matter, which permits the carriage of the bacillus by dust; the use of shallow, open sinks by typhoid patients without disinfection of the dejecta, which renders possible the carrying of contagion by flies, an often present and too much overlooked source of danger; hospital contagion, a danger greater than is generally supposed; the sleeping of the ambulant cases in the company tents, through which the bedding, clothing and tentage become contaminated; the use of the same cups and utensils, and lack of cleanliness on the part of cooks. That there are other means of communicating typhoid fever than by the use of polluted water is shown by the result of moving a camp, the water supply remaining the same. A change of camp site, even for a short distance, is followed by a diminution of disease, especially typhoid.

The position taken by Major Owen is the correct one. Sanitary matters should be under the care of the medical officer. The prevention of disease is his first care. He can best make use of sanitary knowledge. The means for the prevention of disease are best known to him. Medical officers have a greater knowledge of all matters relating to camp and personal hygiene, and much should be entrusted to their care in the selection and maintenance of camps, except where the exigencies of war may prescribe the location of the troops. More of preventive medicine should be taught the medical officer and then much more should be required of him. He should be given more authority. To him should be entrusted the prevention or removal of all sources of camp pollution. Filth is a most threatening danger. The health of the army depends largely upon cleanliness, and the success of the campaign may depend upon the health and well-being of the troops. Sickness reduces the strength of an army not only by the loss of those who are sick, but by the detail for hospital duty. Aye, even more than this, the depressing influence of the presence of sickness affects the zeal, spirit and confidence of an army. Even those who are not sick are less efficient as soldiers. The medical officers whose duty it is "to investigate the sanitary condition of the post or command" should have something more than the mere privilege of making recommendations that they have no power to carry out—recommendations that the commanding officer, too often uninformed upon sanitary matters, may accept or reject. It is generally the latter, as instanced in the paper of Major Owen, which I most cordially commend.

Dr. Edwin Ricketts said that in no sense can it be claimed that this paper was a political move. It is to be commended for its teeming facts as to superior line officers' vested authority in matters that should be referred to the army surgeon, as superior medical authority, for advice before final decision. It steps forward and into bold relief and deserves much consideration by way of emphasis. It calls "attention" in no uncertain sound to the importance of preventive medicine in selecting army camp sites and in timely changing them, so soon as the army surgeon, who should be referee, sees the necessity of so doing, except when the camp site is held as a military necessity. Then the army surgeon should waive all other considerations. It is shown how much more deadly were the germs of typhoid fever and dysentery in the camps located in the United States, on account of lack of hygienic considerations, than were the bullets of an opposing army in the enemy's country, there being 3116 deaths from preventable diseases, as compared with 1070 for homicide, suicide and gunshot wounds. The cross-road physician would feel himself disgraced and with a ruined professional reputation if he had a mortality following his treatment of typhoid fever that came anywhere near this. The deplorably high mortality in typhoid fever and dysentery can not in justice be laid at the door of the army surgeon. Their results in treatment show a mortality of 7.60 per cent. of all cases. This mortality represents 86.24 per cent. of the total mortality of all diseases. The pleadings of the medical officers with their superiors of the line for a change in camp site were in vain. For these pleadings and suggestions they were to be chagrined and humiliated on account of the lack of consideration that should have been extended them. The fault of this lies within our own ranks, for we lack independence, dignity and determination in not demanding and seeing that we have extended to our profession due respect and due consideration for the services rendered to the service of the United States. Major Owen has proven to us fully the courage of his convictions and the cause for the faith that is in him, instead of remaining in the usual subordinate, submissive quietude of the average army surgeon. It has been wisely arranged by our government that any soldier, as soon as he is found to be suffering from tubercular infection, should be promptly isolated by being taken to one of the national farms for tuberculosis. These farms are especially located for the arrest and possible cure of the disease. On the other hand, the poor and unfortunate typhoid fever patient has been kept within an already infected hospital camp. It was safer to have been a private in the charge on San Juan Hill than to have been in Camp Meade, Camp Alger, Camp Thomas or even Camp Merritt, California. With the amended bill as suggested by Major Owen for presentation to Congress, could the tears of the 3116 mothers and those of the relatives and friends, be presented, I am sure it would have a hearing. Could the 3116 men have had the opportunity, they would have gladly and gallantly responded to the bugle's blast, calling them to the charge, even though every life of them had to be sacrificed. They would have accepted the inevitable as thousands of American soldiers have already done. The 3116 deaths from typhoid were from sanitary neglect. It was not excusable. It can not be condoned, for there was no enemy to fight, no enemy within a thousand miles. There could have been no military necessity in these places of assembly and instruction.

Dr. Frank W. Hendley (Late Surgeon and Major Ohio Volunteer Infantry), said that his observation, based upon acquaintance and conversation with a considerable number of surgeons of the army, was that they do not so much desire increased rank or pay as authority and power to enforce sanitary and hygienic measures. The possession of such authority and power would necessarily include the exclusive control of all property, and transportation of all hospitals, hospital corps, ambulance companies and other subdivisions of the medical service. The present status of the medical officer is well-nigh intolerable. As he can only recommend or make request, his efficiency depends upon the complacency of the line officer with whom he is associated. The medical officer may recognize a certain source of danger to the command and recommend certain action to obviate it, but unless the line officer in command concurs and acts in accordance with the recommendation the surgeon can do nothing except wait for the disaster that is to come and then cheerfully go to work to repair the damage.

At the outbreak of the Spanish-American war it was well known that smallpox existed in Cuba, where the troops were expected to operate; consequently the surgeons in all the regiments in Ohio and probably in all others, recommended vaccination during the period of mobilization, in order that the wounded arms might heal before the active camp life commenced. Fortunately, we had a colonel who recognized the propriety of the recommendation and concurred heartily, even going so far as to punish severely half a dozen men who refused to comply with the order; but one Ohio colonel assumed to know more on the subject of vaccination than his surgeon, and refused to issue an order requiring the operation, saying that he did not believe in vaccination. When this regiment reached the South, however, the dictum of the colonel was overruled

by higher authority, and the three medical officers were compelled to vaccinate their eleven hundred men under the added disadvantages of the crowded tent life, in the heat and dust of the southern camp, and during the work and constant drills which were necessary there; consequently the cleanliness, asepsis, and the rest for the affected arms which was desirable, could not be obtained, and infected arms were very numerous, thus throwing much unnecessary additional work upon the surgeons, delaying the efficiency of the regiment, and, I doubt not, laying the foundations for numerous pension claims. Many such instances might be narrated of arbitrary overruling of medical recommendations with unfortunate results, but time does not permit. Medical officers protested against the location of certain camps and the continued occupation of the same site for lengthened periods, calling attention to the fact that all authorities fix the limit of safety for continuous occupation at two weeks, but their protests and recommendations were frequently endorsed, "not concurred in," and the world knows the results that followed at Chickamauga, Tampa, Tampa Heights, and elsewhere. Colonel J. D. Griffiths, Chief Surgeon 3d Division First Army Corps at Chickamauga, says, "Our Medical Department should be divorced from the Quartermaster's Department. As a matter of fact the Quartermaster's Department is largely at fault for much of the trouble, and, while satisfactory for a small army in time of peace, when built upon and expanded as required for an army ten times as large, it failed absolutely and went to pieces. During the hot summer months 75 per cent. of the command still wore the heavy woolen clothing. Insufficient tentage was issued, resulting in overcrowding and this was a cause of much of the subsequent sickness." To these remarks I would add that during the first few weeks it was impossible to secure lumber for tent floors, such requisitions being always disapproved, and as for the tent crowding it was frightful at all times. Many of our men were still in the little shelter tents, well named "pup-tents" by them, all through the rainy season at Port Tampa City. Not until August could tent floors be obtained by our regiment. Requests for disinfectants were met by harsh instructions to read the Regulations, which provide as follows: "The routine use of disinfectants is prohibited." Later when public indignation was aroused against the conditions prevailing, all these supplies were issued freely; but at that time it was like locking the stable door after the horse had been stolen. When at Columbus and still under state control, a liberal supply of chlorid of lime was supplied and used in the sinks; but as soon as we were mustered into the service of the United States, this stopped instantly, because, under the Army Regulations, we were required to cover the contents of the sinks three times daily with dry earth, notwithstanding the fact that at that time it was raining every day, the camp was a sea of mud most of the time, and the sinks half full of water. Surgeon-General Sternberg himself, in his Presidential Address before the Association of Military Surgeons of the United States, in 1895, after commenting upon the mortality during the Civil war, predicted that the sickness and mortality from typhoid fever, dysentery and traumatic infectious diseases would be much less in any future war, but made an important qualification of his prediction as follows: "The extent to which this may be accomplished will depend upon the preparations we make in advance and upon the success we have in obtaining the intelligent cooperation of officers in command of troops in carrying out the recommendations we may make."

On the subject of control of all property and transportation, the defects in the present system are most conspicuous, and Major Owen is undoubtedly right when he calls attention to the complications that might arise under the provisions of the Geneva Convention. The distinction between the European and the American meaning of the word "ambulance" must be carefully borne in mind. In our country it means simply the ambulance wagon, whilst abroad it means the entire field hospital. In our army, under the present system, nothing is exempt from capture except the ambulance wagons, the sick men and their medicines, in addition to the surgeons, hospital corps and nurses. The enemy may legally take the tents over their heads, the cots on which they lie, their food and clothing, their cooking outfit, their wagons, horses, mules, and practically all the hospital supplies, except the medicines and ambulance wagons. And all this simply because tentage, cots, wagons, etc., belong to the Quartermaster's Department and nothing of the Quartermaster's property comes under the provisions of the Geneva Convention. The Hospital Department occupies a position of dependency upon the Quartermaster's Department for absolute necessities. Ordinarily these are supplied freely, but just when they will be most urgently needed, then the Quartermaster will be unable to supply them, and there lies the fatal error of the situation. Just at the time when the surgeon may be asking the Quartermaster to give him more tentage, wagons and mules, the Quartermaster, in the exigencies of the occasion, may feel it necessary for the public service to take away what he has already given. If ammunition and other supplies are needed at the front, the Quartermaster will certainly keep his wagons for that purpose or hold the tents to keep supplies in, rather than issue them to the Hospital Department. The preservation of the fighting line will be considered as of more importance than the comfort of the sick. Over in the Philippines the captain of a company marching all day in the rain reprimanded his men when he found they were covering their shoulders with the flannel cloth given them to cover their rifle locks, saying, "keep your rifles dry, the government can get plenty more men in your places, but it can not get Krag rifles in the place of those you spoil here." How many times has it occurred that when the surgeon asked for wagons to haul ice or water for the hospital, he was told by the Quartermaster that all the wagons were engaged in hauling wood! General Sternberg had his supplies ready at Tampa, but under the Regulations he had to depend upon another department for their transportation to Cuba and that transportation he could not get. If General Sternberg had possessed his own means of transportation for his department Clara Barton could not have made the observation she did. Under present conditions if we go to war again, the sad experiences of the Civil war and of the Spanish-American war, the needless suffering and want endured by the sick and wounded, will be repeated and we will have to depend on outside volunteer relief organizations to do the work that the regular Medical Department could and would do if their hands were not tied.

The system is faulty, therefore the results must be bad. It will never do to depend on volunteer civil organizations to do permanent work in a military campaign. The Sanitary Commission did noble work during the Civil war, but that was a generation ago before our knowledge was in any degree perfected. The National Red Cross helped very much during the Spanish-American war, but their aid should have been unnecessary. Their hospital ship was the first vessel to sail into Santiago harbor and its cargo was a literal godsend to the people there. During the Franco-Prussian war the French Red Cross Society undertook to care for the sick and wounded of the army and established numerous ambulances as field hospitals, but those in charge were compelled to admit the system was incorrect. One says: "The sanitary service of the army should have an organization wholly military and in no way civil, especially on the battlefield;" another says, "There can be no place in any well-regulated army for a volunteer health service." If my information is correct, France has recently made the Medical Department of her army an independent, autonomous department well organized for effective service. Our Medical Department should be so complete that outside interference, well meant as assistance, but nevertheless an intermeddling which causes confusion, will not be necessary and therefore will not present itself. Dr. Tripler, in commenting on some of the difficulties arising during the Civil war, says: "Certain persons suddenly smitten with a more intricate knowledge and thorough perception of the duties and administration of the Medical Department than I had been able to acquire in thirty years of experience and study, obtruded their crude suggestions, marring where they could not make, and paralyzing where they attempted to quicken, succeeded by their uninformed zeal. They, inno-

cently enough, perhaps, but none the less unfortunately enough, succeeded in defeating the measures I had much at heart, had carefully contemplated and intended to carry into effect at the proper time." Not only is this outside interference often irritating, troublesome and non-effective for real good, but it certainly is humiliating for a great nation to be obliged to depend on aid societies and charitable persons for ice and other necessary medical supplies. There will always be ample room for the charitable organizations to do good work in the large base hospitals and among the sick and wounded sent to their homes, but in the field hospitals and in the regimental dispensaries the Medical Department should have the exclusive management of affairs.

By the establishment of the Army Medical School and the Naval Medical School, facilities were provided for the complete training of medical officers for their special work; thus by the creation and excellent development of the Hospital Corps, the Medical Department secured a permanent body of trained, intelligent helpers under its exclusive control, and finally, by the adoption of the trained female nurse system, it perfected and completed its facilities to care for the sick so far as the personnel of the working force was concerned. If now the defects pointed out by Major Owen can be remedied, we shall have a Medical Department which will be a model for the nations of the world.

Now just a few words upon the relation of this subject to the National Guard and the State Medical Department. The nation must, of course, depend upon the National Guard to swell the army to effective strength in time of war and will always be the training school of popular military knowledge. In order that the transfer from state to federal control may take place promptly and easily, the National Guard in its organization, equipment, discipline and instruction must be identical, as near as possible, with the regular establishment. The physical examination of recruits must be thorough and rigid, based closely upon the rules laid down in Tripler's Manual. The Medical Department must be removed from the influence of politics or personal favoritism, and detached from local regimental control. That is, medical officers must be members of the state medical department instead of mere regimental staff officers. They must be appointed only after rigid technical examinations before a board of medical officers, re-examined after three years' service for promotion to captaincy, then again examined at the end of five years for promotion to surgeon-major, provided a vacancy exists. The hospital corps likewise should be enlisted as members of a state hospital corps under exclusive control of the Medical Department. The hospital stewards should begin as acting stewards and secure promotion by examination after one year, the same as in the army. The matter of detailing surgeons, assistant surgeons, stewards, and hospital corps men to serve with the various regiments should be very simple. The above plan is in operation in the states of Minnesota, New Jersey and Massachusetts, so far as state laws permit, and it is found to work in a satisfactory manner. What is urgently needed is uniformity in all the states, and this can only be secured by enactment at Washington of laws that will make the National Guard a secondary or reserve part of the army, thus insuring thorough military control and thorough inspections with power to weed out triflers and incompetents and to build up an effective organization that will stand ready to march at short notice from the local armories direct to the field of operation.

But coming back to the Medical Department: with the organization I have suggested and the use in that organization of all blanks, forms, reports, requisitions, etc., precisely as used in the army Medical Department, substituting only the name of the state in place of that of the United States, and with medical supplies of the same nature, obtained and expended under the same regulations, the terrible bugbear of "paper work" will not be a burden and "red-tape" will not be complained of when the guard is suddenly called to active duty, because the forms will be familiar and the great benefits of the much-dreaded red-tape will be known and appreciated. With medical officers and stewards thus made familiar with the forms of paper-work and the details of Regulations, the Volunteer Medical Officers will be ready to at once work hand in hand with their brethren of the regular service and would cease to merit the title of "fool volunteer."

Dr. Charles H. Castle (Late Captain and Assistant Surgeon First Ohio Volunteer Cavalry, Spanish-American war) said: An experience of some seven months with our army hospitals in the field leads me to unqualifiedly endorse Major Owen's demand that the Medical Department shall be taken from its present absurd and disgraceful dependence upon other departments for its supplies and transportation. There is a publication issued by the government called the United States Army Regulations, and during my first two months in the service I studied this assiduously, but notwithstanding the study I do not think that the full hideousness of its absurdity struck me until one day the ordinance officer, mind you, the man who deals in ponderous death-dealing weapons—in shot and shell and tons of smokeless powder, and in seige trains miles long—came around and gave me a knife and fork and spoon and made me receipt for them!

Major Owen refers in particular to the conditions in the large camp at Chickamauga. Thanks to the liberality of the State of Ohio and some personal friends of the regiment, and thanks also to the fact that we were camped on a sunny plain with good natural drainage, the First Ohio Volunteer Cavalry to which I was attached was almost independent of the government it was serving, in the matter of medical and surgical supplies; as late as the month of June, three months after the regular forces had established themselves in this camp, our regimental hospital had to lend to the headquarters hospital of the Commanding Major-General, mentioned in Major Owen's paper, the necessary surgical dressings for an operation for extirpation of the inguinal glands! The only possible way of accounting for this dearth was that the Medical Department had to depend upon the Quartermaster's Department for transportation, and that department had its mind and its box-cars filled with uniforms, and boots and shoes and tents. Speaking of tents allows me to record the manner in which the Medical Department of the United States Army sometimes gets tents for its typhoid fever patients—and sometimes does not. You will perhaps pardon me for quoting from the medical history of the First Ohio Cavalry which I had the honor to read before you some two years ago. During the first ten days at Camp George H. Thomas, the medical officers of the regiment had two difficulties to contend with; one was the delay in furnishing the troops with fresh beef, keeping them on the travel ration known among the soldiers as "canned giraffe" because it seemed to be all neck, until their hitherto untried digestions were thoroughly upset; and the second was the difficulty in procuring hospital tents. The two medical officers were each entitled to a wall tent, but for the sake of the sick we were obliged to bunk together and give up one of our 8x10 tents as a hospital. Repeated requisitions made by Major Bunts failed of response, until one of our majors of the line, an ex-officer of the regular artillery, discovered that he had in the chief quartermaster an old friend, and his personal solicitation accomplished promptly what a requisition "through the regular military channels" was powerless to effect. Two hospital tents were therefore given to us, and never, from that time, the last week in May, until the 20th of September, when I turned them over to the Depot Quartermaster at Tampa, failed to leak whenever it chanced to rain. These tents were inspected at least once at Chickamauga, and condemned, but were never replaced.

The regiment had left Chickamauga just as the violent epidemic of typhoid had begun there, and had proceeded as ordered, to Lakeland, Fla. For the ten days following our arrival at Lakeland we received our daily addition of cases of typhoid, all cases dating back to Chickamauga, and the additions ceasing as we reached the limits for the period of incubation. Thus on the 18th we received 2, on the 19th 2, on the 20th 2, on the 22d 3, on the 23d 2, on the 24th 1, on the 25th 2, and on the 26th 2. By July 22 we had 12 in the hospital, just filling it; by the 23d we had 14 in hospital, overfilling it. The hospital was cleared of all cases but typhoid,

for we knew of typhoids in quarters that needed attention. Requisitions were made on the Quartermaster's Depot at Tampa, and after a delay of a week, we received one more tent. So that on July 27, when, we may say, we harvested the entire crop of the Chickamauga epidemic that we had brought with us, we had 18 in hospital, filling it, and 34 in quarters, 12 of which latter were typhoid. Being in quarters means lying on the sand floor of a tent, with one blanket under you, and one blanket over you, not at all a bad bed in summertime; but it also means getting up and going to the cook tent every time you want a drink of water, and walking one or two hundred yards outside the confines of camp every time you have one of those frequent typhoid stools, and it became my melancholy duty to make a postmortem examination of a private in the First United States Cavalry—our neighbors—who died of exhaustion from this cause. Early one hot, damp morning this patient walked from his quarters to the sink and back again, laid down, and died an absolutely unnecessary death. The postmortem showed the characteristic lesions of typhoid fever in the second week occurring in a man previously suffering from marked inanition.

About this time there came to us, on behalf of the Army and Navy League of Cincinnati, a lady of education, refinement and tact, and one absolutely devoid of the hysteria that unfortunately afflicted so many of the ordinary camp visitors; she was full of sound common sense that she had gathered in sojournings in various parts of the world. This personal inspection on the part of the Army and Navy League made it the most valuable agency of the kind that I know of, not excepting the Red Cross Society. The camps of the brigade were inspected and the situation discussed, and the need of tents, cots, hospital furnishings, milk, eggs, etc., were acknowledged. Hospital tents had been requisitioned for by Major Bunts, but could not be had, as the Quartermaster at Tampa asserted that all available tents had been given to the new West Tampa Fever Hospital and to the depots at Fernandina; cots could not be had presumably for the same reason, and the limited supply of cots in the village of Lakeland had been exhausted; milk and eggs were being bought by the money supplied by Cleveland friends of the regiment. This business-like angel of the Army and Navy League went to Tampa, obtained an interview with the Quartermaster, and a promise of the necessary tents—the second time in our short military history where an unofficial interview of an outsider accomplished promptly what the requisition "through regular military channels" had totally failed to do. I met the lady the next day in Tampa. We went together to the Quartermaster's office. I stated my errand to the assistant temporarily in charge—the procuring of hospital tents. He politely refused my request on the grounds that he had none. I represented the urgency of the case, the large number of our sick, and the character of their illness. Still a refusal. Then the lady interposed; she announced the promise made by his chief the day before, and the gallant assistant went to the telephone, called up the Quartermaster's Depot, asked how many hospital tents they had, and directed that four be sent at once to the First Ohio Cavalry at Lakewood.

Having seen, now, how the Quartermaster's Department aids the medical officer in his daily visits to the sick, let us see how another department discharged its duties toward the dependent Medical Department. The methods of feeding the sick in the hospitals of the armies of the United States are practically as follows: When a soldier is sick or wounded and is transfered to a hospital, the Commissary Department subtracts his rations from the total amount going to his company, troop or battery and is supposed to send the ration to the hospital in which the soldier lies; and as even the United States Government knows that sick men frequently need dissimilar food from well men, provision is made that at the request of the surgeon in charge, the Commissary Department shall buy this ration from the hospital, or, in other words, shall furnish money at the rate approximately of seventeen or eighteen cents a meal, so that sowbelly, onions, hard tack, and coffee can give way to milk and eggs. Notwithstanding this express provision of the Army Regulations, the Chief Quartermaster at Camp Thomas, Chickamauga Park, Ga., flatly refused to purchase these savings made by our hospital, though frequently requested to do so by Surgeon-Major Bunts through our regimental commissary. I do not know his excuse. The better his excuse the more is exhibited the inherent viciousness of this detestable system. Our sick men were fed milk and eggs by the women of Chattanooga, and every morning our ambulance could be seen along with a long line of other medical mendicants outside the door of their commissary depot, where they were performing the functions abandoned by the men of the War Department of the United States. That this most peculiar and roundabout method of supplying hospitals with food has its disadvantages, to say the least, was illustrated again in our hospital at Lakeland, Fla., when the Second Provisional Cavalry Brigade of the Fourth Army Corps moved north and left me under the pines of Florida with seventy sick men in bed. The brigade commissary did all he could for me; he directed the commissary officer to leave rations with me for thirty days for the whole number of sick. These hideous things could not be eaten by typhoid fever patients and must be sold to purchase milk; but every commissary sergeant in the brigade had been trading sowbelly, coffee, flour and baking powder to the neighboring "crackers" for fresh vegetables for six weeks past, and when I came to sell I found the market overstocked and prices ruinously low. During our mad quest for purchasers almost all of our perishable articles, like potatoes, onions, hard-tack, etc., spoiled, for they had no shelter, so that our total realization from these rations was not enough to keep our hospital going one week. It is true that an order was promulgated from the Adjutant-General's office on Aug. 15, 1898, allowing to the hospitals from the funds of the Commissary Department, sixty cents a day per patient. As soon as I discovered this I made application for the allowance. In the interval before its receipt, Dr. Partello, the resident agent of the Red Cross Society at Tampa, visited me and when I told him that I had made application for the sixty cents per day, he deplored the fact, told me that I had better not accept it when it came, and that it would be an almost endless source of annoyance and confusion to me. I regret to be compelled to state that the predictions of the good Doctor have been fully verified. They compelled me to pay back out of the sixty cents the full value of all the rations that had spoiled or been sold at nominal prices, so that really the net result of my application was abundant correspondence, voluminous reports, severe aggravation of the surgeon, and unabated, unappeased hunger of the typhoid convalescents. The regular medical officer in charge of the West Tampa Fever Hospital, having had seven years' experience of Departmental methods, exhibited a degree of skill and tact in his managment of this matter worthy of all admiration. He drew his sixty cents per diem for his patient and lodged it safely in the bank, so that he could say to any inquiring newspaper man or anxious camp visitor: "See, I am abundantly supplied with funds," but as he continued courteously and gratefully to allow the Red Cross Society to purchase all his food and other necessities, his final reports consisted merely in handing the Government money back again practically untouched; and he had gratified the charitable contributors to the Red Cross fund in the knowledge that it was their ministrations that kept his mortality down to 5 per cent.!

The first disease that enters a military camp is diarrhea; in the midst of a campaign, whether the business in hand be fighting, or seige, or only garrison duty, the diarrheal diseases absorb by far the greatest number of "sick and wounded." The story is the same whether the campaign be a tropical one like ours in Cuba, or amidst the ice and snows that confronted the allied armies of the Crimea. Macleod says of the terrible winter of 1854-1855, that the percentage of sick in eight army corps was 73 per cent., and on another page his figures show that 66 per cent. of the sick had typhoid fever. It is then but reasonable to demand that the medical officer, the sanitarium, should designate what food should be furnished to troops, and that he should have a chance to inspect this food before it reaches the hands of the regimental commissary. At this

latter point it is often too late to prevent harm being done. I have frequently had to condemn food in a troop kitchen right under the eyes of hungry soldiers, who, I was sure, felt no gratitude whatever as the poisons were removed, as there was practically very little else that was palatable left to eat. Digestive disorders, then, as we see, sometimes deprive a commanding officer of one-half of the men sent to him by his government as fighting men. Improper food is in nine cases out of ten the cause of digestive disturbances. Should no one else approve, the commanding general should be grateful if the medical man should step in and by a proper supervision of the food supply, keep to the fighting line at least ten, twenty, or thirty more men in every hundred. It is not difficult to fix the status of the beef that was issued as a factor in this indigestion. We never saw any of the canned roast beef that has produced such a controversy. None was ever issued to the regiment at Chickamauga, and at Lakeland our Commissary heard so many complaints of it from the regulars who were our neighbors, that he refused to touch it and always demanded as the meat of his travel ration the canned corn beef or "canned giraffe." As for the refrigerated beef, it was very difficult to keep, and decomposition with the formation of ptomaines sometimes took place in an hour or so; I have condemned in a cook tent at noon, beef that had passed inspection at 10:30 or 11 a. m. I condemned several tons of this refrigerated beef at Lakeland.

The soldier of the republic must not be regarded only in the light as of food for powder. He is not a conscript, but voluntarily puts on a uniform which he has a right to expect will secure to him all the efficiency possible in fighting his country's enemies, and when that duty is over, if unwounded, he should return to his productive activities a healthy man. Suggestions for specific remedies must come from the experts; the medical officers of the regular service are the only ones who are well enough acquainted with the conditions both as they exist and as they should be, to be able to formulate proper plans. We know now that in at least one of our wars, the Spanish-American war, the medical officer had more work to do, and, considering his shamefully inadequate means, did it better than any other officer in the service, not even excepting the innumerable heroes of San Juan Hill. And one other thing: we know that the war against the Spaniard was a puny, miserable affair in comparison with our war against typhoid; for in this latter, those who should have been our allies aided the enemy. There are perhaps two other considerations that should claim our attention, though they may not bear directly upon Major Owen's contention. The first is that while the army Medical Department should be absolutely relieved from its present crippling dependence upon an overburdened Quartermaster's Department and from the Commissary Department, it should at the same time set its own officers free from a childish dependence upon their chief at Washington.

Finally, the strength of a chain is only the strength of its weakest link, and one of the links of the chain we are considering is the private soldier. The private soldier is usually a very verdant individual and in the calf stage of existence. He will go without camp bounds and drink of forbidden water and eat of forbidden and monstrous thinks sold by hucksters, and now that the canteen is abolished, he will get out of the garrison and drink of vile and forbidden whiskey. The private soldier does not know, and I have never heard that any provision has been made to instruct him, until after he gets sick, when his surgeon has the opportunity to give him some bedside instructions. When I was in service, the commanding officer of our regiment requested the medical officers to deliver occasional lectures at the daily Officers' and Non-Commissioned Officers' School, and I do not know of even this being done in any of the organizations camped in our neighborhood. These instructions should be extended to all and should be held to be an extremely important part of the schooling of the soldier, especially when we know that in all armies in all times, more men have perished from disease than from wounds. In fact, the saying of the old prophet that "they who take the sword shall perish by the sword" never has been correct; and the proper rendering of that biblical verse should be "they who take the sword shall perish by diarrhea." This is true, but it is not creditable to the American people and the twentieth century, and it probably can be stopped, but only in the way which Major Owen's paper indicates.

Dr. W. O. Owen (Major and Surgeon, United States Army) in closing the discussion, said: That which I tell you is no new story, for Irving C. Rosse said some years ago, "If the army medical officer were so fully aware of the importance of prevailing disease and the efficacy of judicious sanitary measures in their prevention, how does it happen that a state of affairs so completely opposed to the first principles of hygiene has been permitted to exist? An answer to this question is found in the unsettled relations existing between the military and medical authorities. In former days the military authorities held that the duties of a medical officer were to treat the sick and wounded, and any recommendations bearing on the general management of the men were deemed intrusive and resented as an interference with the province of the commanding officer. 'Medical opinions are very good when called for' was said to the senior medical officer in the Burmese war; and in the Crimean war, Inspector-General Alexander was informed by a general of division that he 'had better keep his suggestions and strictures until asked for.' It was not within the power of the medical officer, as at the present day, to remedy such evils, and if the suggestions were acted upon at all, it was owing to the common sense or the good feeling of the Commanding Officer."

The above is a very bitter statement of a truth existing in the past. That such a condition can exist may to-day be questioned. Yet a friend of mine, a gentleman who was born in the city of Cincinnati and is a friend of many present, informed me that in 1898 he reported to the general in command of the camp in which he was on duty that the camp was in bad condition and that an epidemic of typhoid was threatening. The answer that he received was an order to leave the general's tent and not to return to it unless he was sent for. How well the medical officer was listened to in the Crimean war is shown by the fact that many regiments lost over 10 per cent. of their strength, some 45 per cent., some 75 per cent., and one lost more than its average strength. It was in this war that the inspector-general was told that he "had better keep his suggestions and strictures until called for." It was in this same war that 20,000 pounds of lime juice were held for future use while scurvy was disabling the entire force.

It is not my idea to attack any man for the past, but to tell of the past that we may be enabled to see more clearly what is needed in order that we may be able to so draw a law that the responsibility may be fixed definitely on some one man, so that he may suffer for his carelessness, or that he may be removed for his lack of ability to control matters which he has been appointed to superintend. Have a law so drawn that it fixes definitely the responsibility. The bill I offer will do this, for the sixth paragraph puts in the hands of the Secretary of War to say when and under what conditions the line can take away from the Medical Department the responsibilities placed upon them by this bill. I have offered this only as a thought in the right direction; if any one will better it, I shall be grateful. My belief is that the line should at all times have the right to take upon their shoulders an absolute disregard for all sanitary law, but that when they do, that they should do so with a direct personal responsibility under the law for the accuracy of judgment used as shown by the results attained. I can not think that men should be subjected to unsanitary conditions in camps of assembly, in camps of instruction, or in war time when the approach of the enemy is not to be dreaded. Sanitary dangers like all other dangers must be taken, when in the opinion of the man in command it is necessary to do so for the general good.

I desire to call attention to General Orders 100, 1863, the last part of 116 says, "An honorable belligerent allows himself to be guided by flags or signals of protection as much as the contingencies and the necessities of the fight will permit.

117: It is justly considered an act of bad faith, or infamy or fiendishness, to deceive the enemy by flags of protection. Such act of bad faith may be good cause for refusing to respect such flags." The above was taken from the Army Regulations published the year before the United States became a party to the Geneva Convention. Yet, with a feeling of this sort published to the world, the hospitals do not have their own transportation. The United States, in the face of the Geneva Convention, still supplies the Medical Department with Quartermaster's transportation, tentage, etc., all because of the mistranslation of the French word "ambulance." The French regulation designates what constitutes an ambulance, giving the allowance of men, wagons, etc., which each class of ambulance shall have. Thus it is that the medical officer flying the Red Cross flag of the Geneva deceives the enemy, for the enemy does not know that all of these tents, wagons, horses, etc., which go to form an ambulance in the United States Army belong to the fighting force and that the fighting force is obligated, when their needs require, to take this material from the ambulances for their own use. They have the right to compel the Medical Department to again receive this property and again protect it from capture by flying over it the Red Cross flag of the Geneva Convention, when their necessity has passed. And hence it is that I have said that the Red Cross flag is a menace to the medical officer flying it over Quartermaster's property, which constitutes so large and important part of the ambulance or flying hospital of the United States Army.

So often has the thought been repeated to me that I am advocating a double-headed command, that I again feel called upon to state that I have insisted and still insist that the command continue to rest in the line where it belongs. I do, however, advocate that the Medical Department shall be made responsible for the sanitary condition of the army, and that penalties be attached for failure to avoid unsanitary conditions; that the right shall rest at all times in the line of the army to take this responsibility from the shoulders of the Medical Department to their own, taking with the responsibilities the penalties provided; that a full justification for their action shall always be the presence of the enemy and the dictation of military necessity.

Dr. J. C. Oliver moved that a copy of Mr. Hay's bill be sent to the Committee on National Regulation of the Ohio State Society with the endorsement of the Academy of Medicine of Cincinnati. Carried.

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting, held at San Francisco, September 24.

Dr. D. W. Montgomery in the Chair.

Dr. Dudley Tait showed the necropsy specimens from a patient upon whom he had made a gastrostomy for cancer of the esophagus. The method employed (Poirier's operation) was briefly as follows: Incision through the rectus under local anesthesia; withdrawal of a cone of the muscular wall of the stomach and fixation of basis of the cone to the parietal peritoneum. A small opening is made at the summit of the cone, penetrating only the two outer layers of the stomach. This is easily done, for when the stomach wall is held between the thumb and index finger the mucous layer rolls away from the outer layer. The mucous layer is then pushed inwardly by blunt dissection, which is always bloodless. A small opening is made into the dome of mucous layer thus formed and a number fourteen or eighteen French catheter introduced. Stitching the edges of the outer cone to the skin, and closure of the remainder of the wall completes the operation, which seldom requires more than ten or fifteen minutes. The result in Dr. Tait's case was excellent; for eight months there was no leakage, and after that, leakage occurred only during intervals of gastric disturbances as manifested by hypersecretion and hyperacidity. The patient was able to take food—liquid and solid—by mouth shortly after the operation and continued doing so for four and a half months. Death from pulmonary congestion occurred thirteen months after the gastrostomy. The specimen showed the disappearance of everything resembling a canal. It is more than probable that this condition occurred early and that the continence was due to the folds of mucous membrane converging at the orifice in the stomach.

After having made seven gastrostomies by different methods, Dr. Tait gave preference to the valvular methods, among which he mentioned Fontan's and its modification by Poirier. Whatever be the method adopted the stomach opening must be very small, and in the majority of methods the tube should be introduced only at the time of feeding. Operation in two stages was dangerous as a long list of complications had demonstrated. Cocain anesthesia was a great improvement. Dr. Tait advised getting the patient up as early as the third day. Roux, of Lausanne, insisted strongly on this proposition in all of his cases of gastric surgery. The return of permeability of the esophagus after gastrostomy was due to the gradual disappearance of the fibro-stenotic process involving the tissues contiguous to the neoplasm. A similar condition was found in rectal growths after colostomy. Dr. Tait spoke briefly of experimental work he had done in view of permitting the patient to take food by the mouth in cases of stricture of the esophagus. The plan consisted in anastomosing the greater curvature of the stomach to a point on the esophagus situated above the stricture. He found that traction on the cardia invariably caused grave respiratory changes, although it was possible to dissect free and bring down a certain portion of the esophagus. Operation from behind was entirely unsuccessful.

Dr. Howard Morrow presented a man with a sarcoma on his forehead. The growth began two years ago, in the skin, at the root of his nose and was removed by a paste. Two months ago it reappeared and now extends within a half inch of the inner canthus of the left eye. The entire growth is in the subcutaneous tissue and only adherent to the skin at the point of the former scar. The patient was brought before the Academy to get the opinion of the members in regard to the best means of treatment.

Dr. H. M. Sherman said that he had never had to deal with a tumor of that character, in that location, but it did not seem to him that it would be difficult of removal as all the nodules were movable. It was possible that the growth was deeper than one would expect. He referred to the use of Coley's fluid in the treatment of such growths, and the recent publication of a paper by Coley, which cited a number of cases where satisfactory microscopic diagnoses were made, and under the use of the mixture the tumor disappeared. He thought we could not shrug our shoulders at a paper of that kind. Wyeth has stated that an incision could be made over the tumor and the tumor bathed in the fluid, but he thought it was best to remove these masses, and if some were found in front of the frontal sinus they still would be accessible for the use of Coley's fluid.

Dr. H. A. L. Ryfkogel said he had watched three cases where Coley's fluid had been used, but none of the cases were spindle-cell sarcomas. He thought it was advisable to use it for the prevention of recurrence.

Dr. Morrow also presented a man with a chancre on the tip of his tongue, of two months' duration. One week ago a typical roseola appeared on his chest. This patient was presented on account of the unusual position of the primary sore.

Dr. Dudley Tait showed photographs of a case of Dupuytren's contraction, in which all the fingers of both hands were involved. The palmar retraction was both longitudinal and transverse and on the plantar surfaces there existed a slight degree of contraction. The latter feature, noted in two former cases, was considered sufficient to eliminate traumatism as an etiologic factor. The difference of opinion in regard to treatment of this lesion could be explained in part by the existence of three distinct stages or forms of the pathologic condition; in the first, the most frequent, the aponeurosis only is involved; in the second, the skin also; in the third, the joints in addition to the aponeurosis and skin. Dr. Tait had talked recently with several European surgeons in reference to the treatment of Dupuytren's contraction, and found most of them advising radical excision, followed by grafts, in the advanced forms. Multiple subcutaneous incisions, as advised by Sir Astley Cooper and subsequently by Adams, demanded long and painful

after-treatment and were frequently followed by recurrence. In the early stage, massage and constitutional treatment—for arthritism and diabetes—give excellent results in this lesion which belonged to the domain of medicine rather than to that of surgery.

Dr. G. Gross read a paper on "Intra-Muscular Mercurial Injections in the Treatment of Syphilis." After going into the history of this form of treatment, his paper took up the technic of the injections. He preferred calomel to other mercurial preparations, and used a glass syringe with a platinum-iridium needle 5 to 6 cm. long, which could be passed through the flame. The author claimed that the injections were not painful in themselves, but by the third day, very often, more or less severe pain and swelling was likely to develop. He thought that in order to pass judgment on this treatment, one must give it a fair trial, with fair warning to patient, and the splendid results obtained would convert those who would persevere.

Dr. G. Caglieri, in discussing Dr. Gross's paper, stated that he did not think the author had shown any advantage in this method, and he thought there were decided objections to it; he thought the injection always produced some pain, and sometimes violent pain. Six weeks ago a man came to him suffering from marked syphilitic manifestations, who had just given up treatment by another physician because he said he could not stand the pain of these intra-muscular injections. Other methods of treatment he thought were equally as good and not so painful. Of these the intra-venous injection method was probably the best. It was more soothing than the former and not such rigid care was required. He described the technic of the injection and claimed that they were very easy of execution. He used the 1 per cent. solution of cyanid of mercury in 20 m. doses daily for ten days, and then increased to a 2 per cent. solution, gradually lengthening the period between these injections until it is used once a week.

Dr. D. W. Montgomery said that he had but little experience with calomel injections, but that little had convinced him that bichlorid injections were not so painful. He did not think that unless the condition was ungovernable he would use calomel. He certainly would not use it in an ordinary case of syphilis, for one could get along very well with inunction or internal treatment. He had never used the cyanid of mercury.

Dr. Gross, in reply, said that he had made a number of intra-venous injections and had always found them painful. One advantage of the intra-muscular injection was that the effect was more lasting. Regarding the pain he said he had used the injections considerably and only remembered one case where the man did not come back. The method should be tried faithfully in order to prove its efficacy.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of Cough and Pain in Tuberculosis.

The following is recommended in *Amer. Med.*:

℞.	Aq. Aurantii flor.	℥iv	128
	Syr. chloralis		
	Syr. morphinæ, āā	℥i	32
	Aq. laurocerosi	℥iii	12

M. Sig.: One dessertspoonful every hour.

Catarrhal Conditions of the Female Genital Tract.

The following has been highly recommended as a very useful general application to the mucous surfaces:

℞.	Ichthyol	℥i	4
	Acidi borici	℥ss	2
	Glycerini	℥i	32

M. Sig.: To be applied locally.

The surfaces having been thoroughly cleansed they should be painted with the foregoing preparation, and when the cervix is involved, a tampon saturated with this solution may be placed *in situ* and allowed to remain for fifteen or twenty hours.

Calcium Chlorid for Menorrhagia.

Lafond, according to the *New York Med. Jour.*, prescribes calcium chlorid in daily amounts of from 20 to 30 grains by the mouth, using the following:

℞.	Calcii chloridi	gr. cxx	8 66
	Syrupi simplicis	℥ii	64
	Aquæ	℥vi	192

M. Sig.: One soupspoonful twice daily for eight days, beginning one week before the expected period.

M. Dalché recommends the following in the form of a pill:

℞.	Ergotin	gr. iss	09
	Quininæ sulph.	gr. 1/3	02
	Pulv. digitalis	gr. 1/6	01
	Pulv. colæ q. s.		

M. Ft. pil. No. i. Sig.: Take one such pill three times a day, beginning three or four days previous to the period and continuing throughout the flow.

Treatment of Neurasthenia.

Lemoine, in *Bul. Gén. de Thér.*, recommends the use of sodium phosphate, administered subcutaneously, stating that it is of service in supplying the phosphoric acid lost by the nervous system. He prescribes it as follows:

℞.	Sodii phosphatis	gr. xlv	3
	Sodii chloridi	gr. xxx	2
	Aq. destil.	℥iii	96

M. Sig.: Inject 30 to 60 minims every other day.

Treatment of Gonorrhea.

As an injection the following is recommended:

℞.	Bismuthi subgal.		
	Pulv. acaciæ, āā	℥ii	8
	Aq. destil.	℥iii	96

M. Sig.: Use as an injection every two hours.

The following is employed by Cabot:

℞.	Plumbi acetatis		
	Acidi tannici		
	Zinci sulphatis		
	Cupri sulphatis, āā	gr. ii	12

M. Fiat tabella No. i. Sig.: Dissolve one such tablet in four ounces of water and use as an injection.

Treatment of Diabetic Pruritus Pudendi.

The physician should always look for diabetes, according to the *New York Med. Jour.*, whenever the pruritus is persistent and does not depend upon obvious local causes. In addition to the diet, if sugar is found in the urine, hot boric acid lotions are recommended:

℞.	Acidi borici	℥iss	48
	Sodii boratis	gr. lxxv	5
	Aq. destil.	Oii	960

M. Sig.: Apply locally as hot as can be borne.

Specific Iritis.

The following is recommended to be given internally in cases of syphilitic iritis:

℞.	Hydrarg. biniodidi	gr. vi	36
	Potass. iodidi	℥iss	6
	Aq. destil	℥ss	16
	Syr. aurantii q. s. ad	℥iii	96

M. Sig.: One teaspoonful three times a day after meals.

Treatment of Appendicitis.

Prof. Bourget, as noted in *Merck's Archives*, outlines the following treatment for appendicitis when once it becomes established: The patient is put on a plain diet, and one-half an ounce of castor oil with 15 grains of salacetol (a salicylic acid derivative) is administered daily. Lavage of the stomach and of the lower bowel is productive of good. A quart of water containing some antiseptic solution may be introduced into the rectum. From three to eight ounces of olive oil may

be injected with this enema. The author uses ichthyol in the above enema in the strength of 4 to 1000. The first two enemas ought to be expelled entirely soon after being injected; later a small quantity should be retained. The enemas may be given morning and evening. During the interval flaxseed poultices are to be supplied over the right iliac region, and if tumor is large five to six leeches are indicated. After two or three days of this treatment the castor oil is replaced by salines as follows:

℞.	Sodii bicarb.	℥ss	2
	Sodii phos.	℥ss	2
	Sodii sulph.	℥ss	2
	Aquæ	Oi	192

M. Sig.: Five ounces three or four times a day.

Dr. Bourget is of the opinion that if the foregoing outline of treatment can be properly carried out that a good number of these cases of appendicitis would escape the surgeon's knife.

Treatment of Ulcers with Camphor.

Schulze, in *Clin. Moderna*, advises the following in the form of an ointment:

℞.	Pulv. camphoræ	gr. xv	1
	Zinci oxidi	℥iiss	10
	Adipis	℥i	32

M. Sig.: Apply locally; or:

℞.	Pulv. camphoræ	gr. xxx	2
	Zinci oxidi	℥i	32
	Olei olivæ	℥i	32

M. Ft. unguentum. Sig.: Shake and apply locally; renew three times a day.

Combination of Trional and Paraldehyde as a Hypnotic.

Rapiteau, as noted in *Amer. Med.*, has observed that the combination of trional and paraldehyde gives a new hypnotic which is four or five times more active than trional alone, and which may be employed for a great length of time without the fear of forming a habit or of cumulative effects. He recommends its administration according to the following formulæ: First make a normal solution of the two drugs as follows:

℞.	Trional	gr. xv	1
	Paraldehyde	gr. xxx	2
	Olei amygdalis dulcis	℥ss	16

Mix the trional and paraldehyde, then add the oil and obtain a solution in a water bath.

As a draught:

℞.	Sol. trional et paraldehyde (normal)	℥iss	48
	Mucilaginis	℥iii	96
	Syr. pruni virg.	℥ss	16

M. Sig.: One tablespoonful at bedtime in cases of insomnia. Each tablespoonful of the foregoing will contain 5 grains of sulphonal and 10 grains of paraldehyde.

The following is serviceable, to be given per rectum:

℞.	Sol. trional et paraldehyde	3ii-iv	8-16
	Ovi vitelli uni		
	Lactis	℥ivss	144

M. Sig.: At one injection for an adult. In the form of a suppository:

℞.	Trional	gr. iii	20
	Paraldehyde	gr. vi	40
	Ol. Theobromæ	3i	4

M. Ft. suppository No. i. Sig.: To be given at night for an adult. For a child these preparations may be given in the following proportions:

℞.	Trional	gr. ¾	05
	Paraldehyde	gr. iss	09
	Ol. Theobromæ	gr. x	66

M. Ft. suppos. No. i. Sig.: At bedtime.

To be given in a capsule either to children or adults in the proper-sized doses, the following form of administration is recommended:

℞.	Trional	gr. ¾	05
	Paraldehyde	gr. iss	09
	Ol. amyg. dulcis	gr. x	66

M. Ft. cap. No. i. Sig.: One capsule three to six times a day.

3. **Laryngeal Tuberculosis.**—Donnellan concludes that primary laryngeal tuberculosis is hardly as rare as has been generally supposed and is quite explicable from a pathologic standpoint. He reviews the literature briefly, notices special points of diagnosis, etc., and remarks on the importance of bacteriologic and histologic examinations.

5. **Kidney Stone Diagnosis.**—The etiology, symptoms, etc., are first noticed by Macrae, who sums up the following as the principal aids as regards the diagnosis: General symptoms, local and reflex; examination of the urine, chemic, macroscopic and microscopic with the centrifuge; percussion over the affected side; the ureteral catheter and sound; inspection of the bladder and ureteral orifices; the segregator. In spite of the possible exception of the actual finding of a stone in the urine, we are not absolutely convinced that we have to deal with a nephritic calculus. Still another question arises as to whether we have one or more stones, and whether, if present, they are in the ureter, kidney substance, etc. He calls attention particularly to the importance of the *x*-ray, and believes the time has arrived when it becomes our duty to submit each and every case of an affection pointing to a pathologic nephroureteral condition to the *x*-ray. A few exceptions to this rule may be made in cases of nephritis following the exanthems, but even here, if the condition exists, the possibility of secondary calculi must not be overlooked. He does not believe in ureteral catheterization as a routine practice and retrograde sounding of the ureter should, he thinks, be relegated to the past.

7.—See also ¶27.

9. **Pulmonary Hemorrhages.**—Bonney has made a statistical study of his cases and reports his observations with special reference to the influence of Colorado climate on hemorrhagic cases of tuberculosis. His conclusions are: 1. Hemorrhage by itself, save with a few exceptions, furnishes no criterion upon which to base a choice of climate, the indications for high altitude in uncomplicated and in not too-far-advanced cases being highly imperative independent of this single manifestation. 2. An exceedingly small proportion of recurrences may be expected in Colorado, although not necessarily reflecting accurately the degree of ultimate improvement secured. 3. Recurrences are more likely to result, and that quickly, in those cases with hemorrhage immediately preceding arrival, and hence the wisdom of a short delay following the hemorrhage before leaving home and unusual precautions as regards rest upon arrival. 4. Primary hemorrhages are comparatively rare in Colorado and usually take place incident to a rapid, progressive, destructive change in cases already with hopeless prognosis, or as a natural result of some external assignable cause, which under proper régime could be avoided. 5. Hemorrhage, while less likely to occur in Colorado than at sea level, is nevertheless, as a general rule, more severe and associated with greater shock. 6. The avoidance of hemorrhage, particularly in the early months of Colorado life, demands a most rigid compliance with detailed instructions.

10. **The Tuberculosis Question.**—Among the subjects discussed by Arrowsmith are those of the heredity of the disease, which he seems to think is effective to a greater extent than many now suppose; at least this is the case as to hereditary predisposition. The method of infection which is alone capable of adequately explaining all the phenomena is that of ingestion, perhaps, in some cases, or a combination of inhalation and ingestion. Few people breathe continuously through their noses and a large proportion of the matters suspended in the inspired air is naturally deposited on the posterior wall of the pharynx and thence inevitably carried downward in the act of swallowing. The gastric disturbances which almost always antedate tuberculosis furnish the opportunity for the bacillus to enter the system by impairing the protective power of the normal stomach secretions. Infected food stuffs are also mentioned in this connection. The sum of our knowledge relative to the antecedent causes of phthisis now seems to be that, given a favorable soil, however produced, and the proper exposure, tuberculosis will result. Just what this soil is, is hard to say, but predisposition may be either inherited or acquired. The pre-tuberculous state is mentioned and it seems to him that all of us who have not tuberculosis, may be said to be in this condition. He fails to see in what the prodromal stage of phthisis differs from that of any other debilitating illness before the characteristic symptoms have appeared. He does not favor the use of tuberculin for diagnostic purposes, considering it not entirely reliable and possibly risky. The actual symptoms on which we may place reliance in reaching a conclusion as to the existence of tuberculosis are enumerated in the following order: Insidious perversion of general nutrition, with gastric and intestinal disturbance, which does not seem to have any distinctive characteristics. A persistent tachycardia is also an indication of commencing trouble in many cases, but one of the weightiest and most observable diagnostic symptoms in his experience is some abnormal variation of the temperature. He doubts the possibility of afebrile tuberculosis. When there is a persisting abnormal temperature range, there may be a question between tuberculosis and some form of malaria, and external applications of guaiacol will sometimes clear up the doubt by relieving the fever of tuberculosis, or leaving that of malaria uninfluenced. Thoracic inspection is of little account in the early stages, though a misshapen, unnaturally small-sized chest is a presumptive indication along with other signs. The apical involvement in the beginning of tuberculosis being to the basal in the ratio of 1 to 500, careful attention should be given to the condition of apex, and while auscultation of the anterior surface may be entirely negative, yet in the supraspinal fossa and along the inner bor-

der of the scapula we may find what we are in search of. In some cases small doses of iodin 3 to 5 gr. three times a day will help to determine the condition. Physical conditions are sometimes apparent during menstruation which are absent at other periods. Unnaturally clear transmission of heart sounds without consolidation is suggestive. Skiagraphy will be a much more prominent diagnostic measure in the future, he thinks, than at present. Occasionally laryngoscopy will reveal the trouble. He says, to recapitulate, that we are justified in assuming tuberculosis on the evidence of otherwise unexplained gastric and nutritive disturbances with persistent tachycardia and fluctuations of temperature, although slight, especially with an increase after exertion—particularly if the personal history gives a coloring probability. We may be absolutely certain of our diagnosis if in addition the slight physical signs mentioned are discoverable, and notwithstanding a history of cough and possibly hemoptysis, we may presumptively discard the probability of tuberculosis if these phenomena are absent. The prognosis of pulmonary tuberculosis is perhaps the most uncertain thing in medicine. He quotes Trudeau's statistics as showing the favorable prognosis in incipient tuberculosis, but the surest way to cure the disease is to prevent it and that the possibility of this is not Utopian is shown by the decrease where sanitary regulations are now enforced. A very important matter is that a patient should be assured of the protection given by an approximately normal condition of the upper respiratory tract. Catarrhal conditions, while they do not run into consumption, increase the liability to it. He condemns the indiscriminate prescribing of change of climate, notices the great success of outdoor life, and mentions a few remedies and methods, such as serum therapy, urea, etc., and protests against the use of cod-liver oil, heroin or other opium derivatives and cough syrups. He thinks, for the relief of cough, that the laryngeal syringe is a better method than any other that may be had. Antiseptic inhalations are of great additional utility.

12. **Consumption in General Hospitals.**—The dangers of crowding general hospitals with consumptive patients is remarked by Stone, who reports cases where tuberculosis seems to have been contracted from such associations. The patients in these wards are in a low state of vitality, especially suspectible to infection, and such infection has taken place.

14. **The Tuberculin Test.**—Casselberry reports a case which seems to him to indicate the decided value of this test as demonstrating the existence of tuberculosis in its bacillary stage. In cases of positive reaction, however, we must bear in mind syphilis, and also certain cases of sarcoma and carcinoma.

15.—See abstract in THE JOURNAL of September 28, p. 856.

16. **Panhysterokolpectomy.**—Complete prolapsus of the uterus and vagina is best treated, according to Edebohls, by panhysterokolpectomy, of which the essentials consist in complete removal of the uterus and vagina followed by operative obliteration or columnization of the bed of the genital tract. The tubes and ovaries are not disturbed if healthy; if diseased, they are removed. Obliteration and columnization of the bed of the removed uterus and vagina is effected by means of from seven to nine buried purse-string sutures of chromicized catgut placed about two to two and a half centimeters apart, and running parallel to each other. Each suture gathers the raw surfaces from the periphery in circular fashion and draws or purses them together in the median line. It is buried by being pushed upward toward the abdomen, while the next suture is being tied beneath it. The effect of the completed operation is to build a solid pelvic floor ten to fifteen centimeters in depth from peritoneum to perineum, and to establish broad apposition of the base of the bladder and the anterior surface of the rectum, conditions similar to those obtaining in the male pelvis. The patient is kept in bed for a week after operation. Recurrence of prolapse is impossible after a correctly and successfully performed panhysterokolpectomy. The operation is indicated in the severest cases of total prolapse, and more especially where other operative procedures have been tried and failed. The interference with further marital relations must be explained, and accepted by the patient prior to operation. In the case of a married woman the husband must also be consulted. Four cases have thus far been operated upon by the author of the operation, all with perfectly satisfactory results.

17. **Strangulated Hernia in Infants.**—Dowd reports a case of a child three months old in which there had been evidence of hernia with symptoms of strangulation, but the hernia was reduced apparently "en bloc" without relief of symptoms and relief was gained by operation. He calls attention to the difficulties of diagnosis in some of these cases. Babies can not talk, and cry for other things as well, and he analyzes the case to show the importance of different symptoms, which he gives in the following order: 1. Tumor; 2, vomiting; 3, constipation; 4, difficulty of urination; 5, restlessness and apparent pain; 6, constitutional depression. Early operation in all these cases has been apparently the greatest safeguard.

18. **Heredity in Tuberculosis.**—King holds the view that tuberculosis produces a relative immunity in the offspring, and that the heredity of the disease is correspondingly diminished. He thinks also that in his observation the average duration of disease in cases where there have been tuberculous parents has been longer and protection should be greater than in patients with no such ancestry. The conclusions which he offers are: 1. The percentage of consumptives having a tuberculous parentage is actually smaller than that having a non-tuberculous parentage, and much smaller than would be more than accounted for by the additional risk of infection to which the former class is subjected. 2. Tuberculosis in the parents renders to no inconsiderable extent an immunity to the disease in the offspring, an immunity which of course is but relative, and not sufficiently protective, but still demonstrable, as is shown by increased resistance to the progress of the disease and increased tendency to recover among this class.

20. **Gunshot Wounds of the Kidney.**—In a case reported by Roberts there was a self-inflicted pistol-shot wound in the front of the left breast, which passed through the depending mammary gland and then into the thorax. The bullet had missed the heart, perforated the diaphragm and injured the liver as it appeared at the time. There was no excessive shock, the pulse was slow, respiration rapid and temperature subnormal. Later, however, the temperature rose together with the respiration and pulse and the patient died after having been under observation about thirty-two hours. The postmortem revealed no injury to the thoracic viscera or intestines, but a groove-like wound was seen in the lower surface of the stomach, not perforating that viscus but perforating the upper end of the kidney, the bullet being found imbedded in the muscles of the back, opposite the first lumbar vertebra. Death was apparently due to slow bleeding of the wounded kidney and septic conditions of the wounded structures. The kidney wound was not suspected during life and operation was deemed hardly necessary.

21. **Gunshot Wound of the Stomach.**—Penn reports a case of gunshot wound of the stomach which was somewhat lower down than President McKinley's wound and was received when the stomach was full. The patient vomited freely as soon as shot, the vomitus consisting of the meal just eaten, together with quantities of clotted blood. He was fed exclusively on the mucilage of the cactus or prickly pear for fourteen days, which was allowed from the first, gradually returning to a full diet. There was never any decided rise of temperature and no evidence of peritonitis. The case is of interest as showing the unaided curative action of Nature occasionally in such cases.

25. **Muscular Atrophies.**—Mayer reports three cases illustrating the difficulties in the diagnosis of the different forms of this condition. One was apparently a case of fascio-scapular humeral dystrophy of the Landouzy-Dejerine type, but presenting certain peculiar features, it having run an acute course, being associated with pseudo-hypertrophy in the thighs and early appearance of contractures. The other two cases also present similar difficulties. He thinks we still cling to the idea of primary muscle disease in the want of more exact

knowledge as to the nervous involvement, which investigations have not yet satisfactorily demonstrated.

26. **Postdiphtheritic Urticaria.**—Walsh remarks on the occurrence of urticaria following the use of antitoxin to which it is credited, and reports a case in which urticaria followed a mild attack of diphtheria in which no antitoxin was used. He believes that careful study of the conditions produced by diphtheria itself will relieve the diphtheria serum from some of the accusations that have been made against it. It has been too much the custom to attribute every unusual symptom occurring after its administration to its agency, while some of these are undoubtedly due to anomalies in Nature's protective reaction against the toxins of the disease.

27. **Lane Lectures.**—This fifth lecture of Dr. Morris takes up the subject of tuberculous skin affections. He still recognizes the utility of the word scrofula as indicating a special delicacy of tissue, making it vulnerable beyond what is seen in the healthy state. He thinks the inoculation of lupus is a possible accident of vaccination, though it must be very rare. Other forms of skin tuberculosis, such as postmortem warts, the possibility of infection from ritual circumcision, tuberculous ulcers, scrofuloderma, lichen scrofulosorum and the various forms of tuberculides are also noticed.

28. **The Tonsils.**—Levy considers that the local causes of tonsillar disease are more important than the symptomatic causes and that the proper management of local conditions would prevent subsequent diseases. When the tonsils appear enlarged it has been the practice to remove them. He asks how we can preserve the protective functions which so many good authors recognize and how we may overcome the conditions and the etiologic factors for which the tonsils are responsible agents. In the majority of instances, especially in adults, complete enucleation of the diseased tonsil should be performed. The best method for this in adults is, he thinks, the galvanocaustic snare and where this is impracticable complete dissection of the diseased tissues may be accomplished by properly-constructed galvanocautery electrodes. In children amygdalotomy has its uses and advantages, and only in those cases where recurrence after a former amygdalotomy has taken place or where there is a diseased condition without hypertrophy, such as is seen in adults, should the more difficult and radical procedure be undertaken. In conclusion he insists that no operation on the tonsils should be performed simply because the structures are not absolutely normal in appearance, but only when distinct and well-defined symptoms exist, referable to these organs as the obvious cause.

33. **Ambroise Pare.**—Cumston's article is an interesting historical account of the life and times of Ambroise Paré.

34. **Cretinism.**—Millet gives a brief account of the facts in regard to cretinism, and also reports a couple of cases which had been treated with thyroid with benefit, but not with complete relief.

35. **Splenic Anemia.**—As far as it appears in this issue, Wentworth's article is a continuation of the discussion of the literature of the subject.

39. **Fibrinous Bronchitis.**—French reports and illustrates a case occurring in his own practice and reviews the etiology —which is not so characteristic—pathology, symptoms, prognosis and treatment of the condition. He considers the prognosis always grave, especially in the extremes of life, and much more serious when it occurs in the course of other affections than in the presence of fair health. He uses carbonate of creosote, in which he thinks he is the pioneer. He was led to use this by his observation of its action on bronchial secretion in other affections and also by the suspicion that tuberculosis might be present in the case. Improvement began immediately after its administration, and while a single case does not demonstrate much and the dose was small, he mentions it as being of some possible value.

40. **Nephrolithiasis.**—Ransohoff notices the diagnosis, treatment, etc., of nephrolithiasis and considers that the tenderness elicited in renal colic on bimanual examination of the kidney is an almost distinguishing feature, even in cases where enlargement can not be felt. He also thinks that uranalysis will do much in the diagnosis, and that decrease in the urine is sometimes of importance. Hematuria is always present, though rarely profuse. While profuse hematuria may follow acute kidney-stone colic, it more generally points to intermittent hydronephrosis, acute exacerbation of a chronic nephritis, and above all to malignant disease. If the colic has passed, the second symptom-group appears, such as pain spontaneously, or caused by pressure, urine changes, and general symptoms indicating the progressive septic changes in the kidney before it has come to proportional enlargement. While no one of these is pathogenic, their grouping is generally such that a correct diagnosis can be made. Pressure pain is much more important than spontaneous pain. Microscopic hematuria in the urine is also of importance. We should also employ cystoscopy to exclude vesical disease and to observe the changes around the ureteral orifice. He has had little positive results with radiography, and has removed quite large stones in which the method failed, but he thinks that in the future he may be enabled to get some positive results. When the colic fails to be followed by the passage of stones the indications for operation are strong, the case is parallel to that of gallstone, and trouble may ensue at any time. We should not wait for suppurative pyelitis or pyelonephritis to compel an operation as a life-saving measure. Nephrolithotomy should be a routine operation; its mortality is low and he thinks that a longitudinal section made along the convexity of the gland is less likely to wound the large vessels, and it need not be longer than necessary to introduce the exploratory finger, and compression of the pedicle of the kidney may be employed for short periods without any harm to completely control the hemorrhage. Drainage is seldom required. When in consequence of irritation from, and secondary infection due to stone, the kidney is enlarged and sacculated, nephrotomy and drainage are the procedures to be adopted, though the results are not so favorable. Nephrectomy is reserved for extreme cases where the disorganization of the kidney is such that it can not be recovered from.

41.—See abstract in THE JOURNAL, xxxvi, p. 1725.

42.—Ibid., p. 1726.

43.—Ibid.

44.—Ibid., p. 1725.

56. **Accessory Thyroids.**—Theisen reports and illustrates a case where there was a large tumor nearly the size of a hen's egg situated at the base of the tongue in a patient who, when young, had a very well-marked goiter and in whom at the present time there is no thyroid perceptible in its proper place. The troublesome symptoms seemed to be due to the size of the growth, but it did not seriously interfere with respiration. It was considered inadvisable on account of its size to operate, but thyroid medication was tried without bad effects and the tumor seemed to gradually decrease. He reviews a number of cases reported in the literature and remarks on the peculiar fact that all cases of accessory thyroid thus far reported in this situation have occurred in women.

69. **Malarial Nephritis.**—Ewing found in 14 fatal cases of malaria seen mostly in Montauk in 1898, extensive degenerative changes in the kidney, once the lesions of hemaglobinuric malaria, but comparatively few or any parasites in the renal vessels. The case here reported, however, shows the clinical symptoms of hemoglobinuric nephritis, with partial suppression of urine, and gives clear microscopic evidence of extreme massing of parasites in the kidney, apparently contradicting Marchiafava and Bignami's deduction that the lesions are not due to such localization, but to some toxic substance eliminated through the kidneys. In this case there was no doubt that the renal lesions were the principal features and that the case was one of true malaria in which the hemorrhagic character was due to massing of these parasites. The extreme degeneration of the cortical tubules is also a peculiar feature. He concludes as follows from the literature and his own

observations: "Microscopical examination of the kidneys of fatal cases of malaria has, then, yielded evidence of three main types of acute renal lesions occurring in this disease. 1. Acute degeneration of toxic origin, often reaching a degree in which exudation of blood serum into the tubules is added. This lesion is responsible for the vast majority of the cases of albuminuria in malaria. 2. An extreme form of acute degeneration, with focal necroses, numerous hemorrhages, and exudation into the tubules of the blood serum and blood pigments. This lesion is seen in cases of hemoglobinuric malarial fever, and it has not yet been found associated with an excessive number of parasites in the capillary vessels. 3. Massing of parasites in the renal capillaries, with extreme degeneration of parenchyma cells, multiple hemorrhages, and exudation of blood serum into the tubules. It seems certain that this type of lesion can occur only in severe estivo-autumnal infections. There is anatomical evidence that in the pernicious estivo-autumnal cases, the three types of lesions may be variously combined, but no good reason for believing that with the benign tertian infection occurring in this latitude any other than the first type can exist."

70. **Influenzal Mastoiditis.**—McCaw calls attention to the frequency of mastoiditis immediately following epidemics of influenza consequent on tympanic infection, which is, therefore, tympano-mastoiditis. The cases seem to be slow in recovery, the clinical picture being one of a very active suppurative process in a tissue of low vitality. In the severer type of cases he believes that la grippe is responsible for more cases of acute suppurative mastoiditis than either scarlatina, measles or diphtheria. From Perez's experiments he makes the suggestion that we may have one inflammation due to inoculation of Pfeiffer's bacillus alone, whereas in the other variety it may be associated with pyogenic organisms, and the virulence of each may be increased. As regards treatment, his best results have been obtained in the hemorrhagic type by rest in bed, free catharsis, leeching in front of the tragus and over the mastoid, and from douching of the canal every two hours. He is well aware that this method of hot douching has been criticised, but it has not been followed by bad consequences and has given him the largest percentage of recoveries. In the suppurative cases he uses early and free incision of the drum, warm douching every two hours with cleansing processes, catharsis and, if this does not relieve the patient in 36 to 48 hours, the case will be one for surgical interference. The amount of destruction which may take place in a short time is very notable. He has seen the entire mastoid in a purulent and necrotic condition with involvement of the facial nerve and facial paralysis in one week from the first ear symptoms. When we feel satisfied that pyogenic disease of the mastoid exists, our duty is to open the cells and not try to palliate or abort. In conclusion he emphasizes that we have two distinct types: "1. The suppurative, which invades the tympanum, antrum, and cells almost simultaneously in an unusually virulent and destructive process, which calls for early surgical treatment and in which abortive measures are contraindicated. 2. The hemorrhagic, with very pronounced symptoms at first, but which yields readily to abortive measures, and, in the writer's experience, only about 5 per cent. go on to suppuration requiring radical interference."

75.—See abstract in The Journal of October 19, ¶143, p. 1068.

77. **Anesthetics for Children.**—Wynkoop reviews the opinions and facts as regards the action of anesthetics in children and comes to the general conclusion that ether can be used with greater safety than any other anesthetic, while the combination with nitrous oxid is of value. Ether alone has few contraindications if properly administered.

80. **X-Ray in Lupus Vulgaris.**—Four cases of lupus vulgaris treated by the *x*-ray are reported by Greenleaf, who finds that this is the most satisfactory treatment for the condition and that repair begins almost immediately, that the danger attending the treatment is minimal, that the surroundings and general condition of the patient are important elements in the ultimate results, and that cases not subjected to surgical treatment react rapidly and ultimately recover, whereas, cases that have been surgically treated, react in a degree of slowness depending on the extent of the previous surgical interference.

82.—See abstract in The Journal of September 14, p. 711.

86. **Pelvic Appendiceal Abscesses.**—Four cases of pelvic appendiceal abscesses are reported by Baldwin, who thinks their opening per vaginam or per rectum is the simplest and most natural procedure and will lead to temporary recovery. If the appendix continues to make trouble, its removal in an interval operation will be attended with an absolute minimum of risk, while to open such an abscess by abdominal incision and across the open peritoneal cavity causes most serious risk and if peritonitis is obviated by extensive packing there is an almost inevitable chance of hernia.

89. **Counter Prescribing.**—Donaldson finds the druggist is better equipped to do counter prescribing than ever before. He has on his shelf proprietary remedies that save him the trouble not only of compounding, but also of selecting. The patient makes the diagnosis and the druggist has the remedy mixed, labeled and guaranteed. He took the trouble recently to make a list from a druggist's shelves of the diseases treated by modern counter prescribing. He found there 18 sure cures for consumption, 22 for rheumatism, 12 for gonorrhea, and special remedies for other diseases such as diabetes, etc., together with numerous shotgun mixtures, called pain-killers, blood-purifiers, or system-renovators that cure all diseases. He says it would not do to say to our patients "do not use patent medicines" for they would think it selfish in those advising them. The only legislation man can conceive that would mend matters would be one to require manufacturers to put the ingredients on each package. The physician should avoid prescribing proprietary remedies in the original packages as it teaches patients to treat themselves and gives them the little knowledge that is often dangerous. There is no need of telling the patient what drugs he is taking. If you listen in a drug store to the people you can hear them ask for quinin, morphin, ergot, calomel, bromid of potash and dozens of remedies of which they have obtained knowledge through the physician. Poisonous or dangerous remedies should be ordered off the market. Among these he mentions a "female regulator" that is put on the market, which is an ideal abortifacient so far as drugs are capable of acting in that way.

93.—See abstract in The Journal of September 21, p. 742.

98. **Nevus Linearis.**—The cause of the streaks in nevus linearis is discussed by Montgomery, who reviews the various theories and reports a case. The view that seems most nearly to fill the requirements is, that nevus linearis originates at an early stage in the development of the fetus when the embryonic layers are still a plastic mass. The disturbing agent, whatever its nature, usually affects what will later become the papillary layer of the skin and usually falls on one or the other side of the median line. Imagining the affected cells or groups of cells to lie in the plastic cells like currants in dough one can see that such a group lying in the region which later becomes the back of the neck, might be pulled toward the median line when the skin closes over the neural canal, and its individual constituents become scattered along this line as the fetus elongates. Another group situated over the place where the limb will afterward bud out, would be stretched along this line with the budding limb, and the line would tend to follow all the twists and turns of the limb as it grew out, exactly as Kaposi has so graphically described. This view would explain the frequent unilaterality of the affection, and its occurrence along the fissures of the body, as along the branchial clefts. There are some objections to this view, but he concludes that, on the whole, it is the most probable one that can be offered.

104. **Convalescence from Functional Nervous Disorders.**—The management of the convalescent stage of functional nervous troubles is discussed by Pearce, who insists on the importance of mental methods, though not dwelling on this phase of the subject extensively. He thinks the patients must be schooled

or educated into self-control. The physical care, that is, the necessity of rest and of exercise to a limited degree, is also mentioned as important, and he thinks the most desirable forms of exercise in this stage of neural disorders are to be in a general way different from those of the ordinary routine of the patient's life; that is, keeping him away from his ordinary mode of thought and from thinking about self. If the patient can be kept off his feet to a certain extent it will be advantageous. As for the adjuvants to mental rest we have intestinal antisepsis, colon flushings, diet, hypernutrition, massage, electricity and avoidance of excitement.

114. **Antrum Abscess.**—Pierce thinks that the ostium and accessory openings of the antrum of Highmore have not been utilized sufficiently in the treatment of empyema. After a few remarks on the anatomy he describes his method of treatment by washing out the antrum and reports a number of cases. In conclusion he says: "1. There is a strong evidence to warrant the belief that in diseased antra, accessory openings are more frequently found than in healthy antra. 2. In a certain number of cases the ostium may be used to irrigate the antrum. 3. We should in all cases, whether for diagnosis or treatment, try for the ostium or accessory openings before resorting to surgical puncture, whether through the inferior or middle meatus, the canine fossa or alveolar process. 4. It is of no importance whether the opening through which we irrigate be the ostium or an accessory opening."

115. **Diagnosis of Adenoids.**—A number of conditions that may cause confusion and lead to diagnosis of adenoids in very young children are enumerated by Chappell. He has not, himself, been able to demonstrate to his satisfaction the presence of adenoids in young infants. Among the conditions which he mentions are lymphatism which may cause enlargement of the cervico-bronchial glands in which the mucosa of the trachea and bronchi are principally affected and which may often be present at birth. In all degrees of obstruction beyond the uvula the infant is obliged to remove the nipple from the mouth every few minutes to get air, but when the obstruction is lower down, the nipple may be retained in the mouth during feeding. When stenosis of the tracheo-bronchial tract exists, sonorous and asthmatic chest sounds may be heard while the child is nursing, which cease when the nursing is over. Lithemic infection is usually confined to the superficial tissues, but may spread beneath the pharyngeal aponeurosis, forming a small retropharyngeal abscess. When infants with a family history of gout or rheumatism have recurring attacks of rhinitis, pharyngitis, trachitis and bronchitis there may be indications that suggest adenoid obstruction. Syphilitic or gonorrheal rhinitis may produce nasal obstruction and congenital atelectasis may cause respiratory symptoms which may sometimes be mistaken for adenoids. Digestive disturbances causing vomiting and regurgitation of milk curds lodging in the nasal passages also give confusing symptoms. Large tongue, though rare, may be a serious cause of respiratory obstruction and Billard claims there is a non-traumatic esophagitis, which may cause considerable pressure on the trachea and larynx. Chappell has had patients in which he could make no other satisfactory diagnosis. Hypertrophic rhinitis is common in children though general among those of more advanced age. Septal spurs, foreign bodies in the nose, etc., should all be looked for in this connection.

118.—See abstract in THE JOURNAL of September 28, p. 850.

124. **Pernicious Anemia.**—From a review of the facts of this condition White concludes that we have in these cases to deal with some agent which increases blood destruction and interferes with blood regeneration both in the marrow and the lymphatic glands, and that it is not of the common order of the infections, from the different responses which the organism makes to it. The resistance of the individual probably plays a very important rôle and he thinks that from the analogous parasitic condition the agent is more likely to be an animal poison or possibly a ptomain than anything else. In short, he holds that we have here a special poison choosing for its seat the whole blood circulation.

128. **Tetanus.**—From the fact that tetanus germs are susceptible to cold and that the reduction of temperature interferes with their vital activity and sporulation, Rogers has employed ice applications in incipient cases where the tetanic conditions had already spread to the trunk, neck and extremities. The arrest of progress in the development of the disease was manifest in a few hours and after four days there was a gradual lessening of the convulsive symptoms which ceased entirely on the fifth day. The patient then suspended of his own accord, the ice treatment. The symptoms returned in thirty-six hours, but with diminished force. On renewal of the treatment the good results followed even more quickly and three days later treatment was permanently suspended. A second case is also mentioned where similar treatment was instituted with like results.

131.—See abstract in THE JOURNAL, XXXV, p. 1425.

134. **Gastrostomy.**—In the patient described by Meriwether there was a carcinomatous tumor of the pyloric end of the stomach and also a cardiac mass obstructing that region. Gastroenterostomy was performed with the Murphy button and gastrostomy as follows: An external opening had been made by an incision of four inches over the inner edge of the left rectus joined by a transverse one from its upper end extending to the left for three inches. A rubber tube was next inserted in about the middle of the anterior surface of the stomach, emerging at the end of the transverse incision through the skin. Two catgut sutures were applied below the opening in the stomach, then six sutures, each one-fourth of an inch further above and below the tube than the preceding one, the sutures being half an inch apart and passing through the peritoneum, then through one-fourth of an inch of the two external coats of the stomach, then over the tube, then through the stomach as before, and then through the peritoneum. A last suture was passed through the two coats of the stomach and then under the tube, making something like a purse-string suture. All these were of catgut. When tied they brought peritoneum to peritoneum and formed a fluid-tight, funnel-shaped canal leading from the skin to the opening in the stomach. The peritoneum was stitched around the portion of the tube where it emerged and the skin and muscle closed by through-and-through sutures of silkworm-gut. One fine catgut suture was placed through the tube where it entered the stomach to anchor it. The patient was fed before leaving the table after the stomach had been washed out. She came out of the operation well, gained in weight and about four months later appeared to be in good condition. Three months after the operation she removed the tube and refused to allow it to be permanently replaced. At one time it was left out thirty-six hours, but there was no difficulty in reintroducing it. Five months after the operation, however, the old difficulty in swallowing returned and she gradually sank, living, however, until November. The button came away on the eighty-first day.

141. **Widal's Reaction.**—Pothier considers the positive Widal reaction of great value and always to be considered as indicating typhoid fever, while a negative result does not mean anything *per se*. While several negative results may strongly point to a non-typhoid case, the clinical course of the disease is a better criterion. He mentions a method of diagnosis used in the New Orleans Charity Hospital, consisting in making cultures from the urine of patients, which is collected in sterile tubes after careful asepsis of the parts and, if necessary, by catheterization. Two or three loopfuls from this urine are planted on an agar-culture tube or in bouillon, incubated for twenty-four hours and then tested with a known typhoid serum as to whether or not it is typhoid. As a rule these cultures are pure.

142. **Spinal Analgesia.**—Delaup briefly reports 22 cases and describes his method of using cocain injections. He has seen but little inconvenience from the operation; perfect analgesia was obtained in 90 per cent. and partial in 9 per cent. In 41 per cent. there were not the slightest subjective or objective symptoms. Nausea occurred in 36 per cent. and there was a slight general malaise for a few minutes. Headache was

the most common symptom, noted in 50 per cent. of the cases, never lasting more than from twelve to twenty-four hours; temperature elevation was of short duration, never above 102 F. Pronounced malaise, chills, depression, and in fact shock, was observed in but one case. Increased pulse-rate is a very unreliable symptom, the nervousness of the patient is liable to account for it. If there is febrile or irregular heart action small doses of strychnin or nitroglycerin may be administered hypodermically. It is a good plan to give a preliminary subcutaneous injection of strychnin with a little morphin. Involuntary defecation took place only once. He is not sure whether the disagreeable symptoms are the result of the drug itself, or the result of disturbance of the nerve centers from increase or decrease of intraspinal pressure. But the method can never be used with a certain class of patients, like children and nervous women, in which the loss of consciousness is essential. While he does not consider it an ideal anesthetic, or that it in any way replaces the general method, it has a special sphere of usefulness in genito-urinary and rectal surgery and surgery of the lower extremities. In many cases of pulmonary, cardiac or renal disease it would be far less dangerous than chloroform or ether.

152. **Vaccination.**—Runyon has little faith in glycerinated virus. He has found it ineffective in many patients and some patients he has known to suffer from subsequent smallpox when exposed. He believes that the humanized virus is best, though it is not certain that its immunity persists longer than that from points. The next best is bovine on bone slips. He thinks that children should be vaccinated in infancy and again in five years, and revaccinated when liable to be exposed to smallpox. In this way they will avoid serious effects from the operation which sometimes occur when it is delayed until ordinary immunity is completely lost.

153. **Hemaglobinuric Fever.**—With the two cases here reported Shropshire remarks in regard to the origin of the condition. He doubts entirely the effect of quinin in producing it, and considers the disease as a primary malignant fever due entirely to the action of the plasmodium. He uses quinin freely in cases with good results.

British Medical Journal, October 5.

Shock in Abdominal Operations. George A. Hawkins-Ambler.—The author does not attempt to give a definition of shock, but quotes a number that have been offered, among the more scientific of which he includes that of Erichson, who describes shock as being due to a general exhaustion of the nervous centers consequent upon extremely violent afferent impulse, and that of Goltz, quoted by Crile, as a vasomotor paralysis resulting from mechanical violence. While we have not a satisfactory definition, we have learned more in regard to the subject and he refers to Sherrington's work, pointing out that operative interference in a healthy animal is followed by a certain degree of apoplasmia or drying up of the blood. The degree of apoplasmia depends to some extent upon the severity of the lesion, but is always considerable and must always be taken into our calculation. With this increase in specific gravity, Sherrington also observes an increase in the hemoglobin content of the blood and increase in the number of chromocytes per unit volume. The ratio of leucocytes to chromocytes was always increased and there were alterations in the proportion of other blood cells. The different nerve cells also give important evidence. Crile quotes Hodge's investigations on microscopic investigations of nerve cells at rest and in fatigue, showing that repeated afferent stimuli exhaust the bulb; the equilibrium of the nervous system is more or less upset. We must differentiate also between shock and acute sepsis, which offers similar symptoms. Some cases of apparent shock are really cases of acute sepsis, and if we look in the mediastinal glands and other organs we shall find evidence of this. Special points, however, here given as important elements in the causation of shock are the matters of time and engorgement and dilatation of the splanchnic area. In abdominal operations in which we are operating in the midst of vasomotor nerves and ganglia which control an immense venous area, the dilatation of which must mean a remarkable difference in the blood pressure throughout the circulation, the effect on the heart might be immediate. The author refers especially here to Crile's work, one of the latest, most practical and suggestive on the subject. Bearing these things in mind, what are we to say about the treatment? The best he thinks is preventive. We should prepare for shock and minimize it by the very best methods. The old-fashioned plan of preparation of patients by a short holiday is an excellent thing in its way. Improvement in the general health should be looked after. We sometimes starve our patients too much before operation and with hot douches, drastic purges, etc., reduce them so that the addition of fear is all that is necessary to bring them to a state of semi-collapse before they get on the table. An empty stomach, desirable as it is in many cases, may be procured at too great a cost. Preliminary injection of saline solution into the rectum before operation may add a great deal to the patient's comfort and improve the chances, or a little brandy with hot water may be of advantage. The question of anesthetics is important also. Any anesthetic may have its action in increasing the shock. Crile finds that he prevents shock by cutting out the afferent impulses, blocking the nerves with cocain, but this is not so easy in abdominal surgery. Hawkins-Ambler's opinion is that the element of time is the most important; Lawson Tait's success he attributes largely to his rapidity in operating. The question of the temperature of the operating room, preliminary preparation, etc., is important, and he says it is a good plan to flood the peritoneum for a time with hot saline solution in protracted operations. The next point is thirst; if we take thickening of the blood as evidence and standard of shock the intense thirst is an indication of it and the practice of starvation in the hope that the thirsty tissues may be compelled to lap up the exudates into the peritoneal cavity to prevent sepsis, and peritonitis may very easily be overdone. Shock should be met by replacing fluids withdrawn from the circulation, by restoring to the dried blood the more spacious circulatory medium in which its cells may move without increasing the friction coefficient. If there is no vomiting, fluids may be given in small quantities by the mouth. Hot water can be sipped, and the very act of slowly sipping has been shown to improve the pulse by antagonizing the inhibitory action of the vagus. Minute doses of brandy and water also sipped at intervals have a very sedative effect. Saline injections given per rectum, or if necessary hypodermically into the veins are advantageous. The difference between shock and hemorrhage is perhaps after all not so great; it is largely the loss of oxygen carriers in the latter case. If the blood is pooled in the splanchnic veins, both plasma and corpuscles are removed from active usefulness. The introduction of saline will largely remedy this. With flushing of the peritoneum to prevent sepsis we shall also promote its resisting powers, and he insists, therefore, on the use of saline solutions. As for drugs, they must be secondary, and as to maintenance of body heat by wrapping the patient, etc., he has but few words to say. Very small doses of strychnia are of value, and also small doses of morphin and atropin given hypodermically before the patient leaves the table at the close of a severe operation.

When and How to Operate on Uterine Fibroids. William Duncan.—The author believes the following conditions call for interference in uterine fibroids: Hemorrhage, when there is severe menorrhagia or metrorrhagia and the uterus is enlarged by fibroids. The first thing to do is to dilate the cervical canal and explore the uterine cavity for polypi or submucous growths. This should be done before resorting to more radical measures. He does not believe much in operating through the vagina, and removal of the appendages to stop hemorrhage or arrest the growth of tumor. Hysterectomy can, he believes, be best carried out by the intraperitoneal method, which has the advantage of showing whether there are any adhesions of the bowel or omentum to the tumor, or whether

the Fallopian tubes contain pus. The second indication for operation is when the tumor is causing pressure on the bladder, the rectum or cervical nerves. When it can be pushed above the brim of the pelvis and kept there, operation may be avoided, but when it can not, nothing but hysterectomy is of use. When a fibroid tumor takes on a rapid growth this is due either to cystic or mucoid degeneration and always calls for hysterectomy without delay. Lastly, when a fibroid complicates pregnancy the risks are greatly increased, though the position of the growth has much to do with this. If the fibroid is situated at the upper uterine segment or is subperitoneal and not impacted in the pelvis, pregnancy and labor may in many cases proceed naturally and terminate favorably. Such cases should not be interfered with. When it occurs in the lower portion of the pelvic, obstructing the pelvic brim, we have either to empty the uterus, to perform hysterectomy, or allow the case to go on to full term and save the child by Cesarean section and then remove the uterus. He would feel disposed in such cases to try abortion first, and if that failed to resort to hysterectomy. The dangers of shock with heart failure and tympanitis from intestinal paralysis are mentioned. In order to prevent the first it has been his custom to administer hypodermically 3 drops of liquor strychniæ, B. P., three times a day for a week prior to and a week after the operation. A nutritive enema after the operation is administered every four hours, with the addition of one-half an ounce of brandy if the patient is very feeble, and, if the flatus is not freely escaping twenty-four hours after operation, an ounce of spirits of turpentine in a pint of hot water is passed high up in the bowel. This may be repeated in twelve hours. He attaches great importance to this and to the strychnia injections. As regards the operation itself, he ties off both the ovarian and uterine arteries on both sides before cutting down the peritoneal flaps; thus preventing loss of blood to any great extent. After the flaps are reflected down to the level of the tied uterine arteries, the cervix is cut across and the tumor removed. Any oozing points in the cervix are tied with catgut, and then the peritoneal flaps are carefully brought together with fine silk in a continuous Lembert suture. Where the tumor burrows between the layers of the broad ligaments and a large cavity is left after their removal, instead of draining this, he carefully whips the sides together from below upward by a continuous suture after all oozing has been controlled and the cases do perfectly well. The abdominal wall is sewed up by three layers of continuous suture, fine silk for the peritoneum, coarse silk for the sheaths of the recti and coarser for the skin. In this way he feels sure that the occurrence of ventral hernia later on is prevented.

On a New Gynecological Position. F. Jayle.—In this note in the *British Medical Journal*, Jayle points out that Scultetus had recommended what is really the Trendelenburg position before 1645, and there was also a drawing in a still earlier, 13th century publication, showing the position during the operation for hernia. What he specially calls attention to, however, is the combination of the ordinary position of the speculum or of the lithotomy position and of the Trendelenburg position. In order to obtain this it is necessary to have a balancing table with a system of shoulder rests, holding the patient in position without securing the lower members, which remain free. This can be used either for examination or operation. It has the advantage of throwing back the intestine, of determining by the entrance of air the dilatation of the vagina, which becomes almost vertical, and finally of stretching the anterior vaginal wall. It greatly facilitates the exploration of the tubes and ovaries, especially the uterus. The introduction of the speculum is very easy and exploration of the vaginal wall is easy, for it is sufficient to depress the perineum either with the finger or with a valve speculum in order to get a good view of the anterior walls always, and very frequently of the cervix. For operations it must be used combined with the lithotomy position. If the patient be put only in a half declivity, vaginal operation becomes much easier. The anterior wall is stretched out and with a weight valve you can press down the perineum, and no assistant is necessary for holding the valves. He specially calls attention to the utility of this method in vesico-vaginal fistula operations.

Ovarian Pregnancy. Hastings Gilford.—The published cases of ovarian pregnancy are reviewed by Gilford, who finds 16 cases and 12 probable ones, or 28 altogether. He thinks that many have been reported under the names of blood cysts, rupture of the ovary and ovarian apoplexy. He asks how conception within the Graafian follicle can take place. One explanation is that the sperm cell enters through the aperture produced by the bursting of a follicle and impregnates an ovum which has not yet escaped. The opening then heals over and pregnancy goes on in the sealed sac. The other is given by Schroeder, who thinks that the spermatozoa may possibly penetrate through the coat of the follicle at its most attenuated part. The former of these, he thinks, is the more probable, though it does not necessarily follow that the rent in the follicle closes.

Further Report on the New Operation for Prolapsus Uteri, with Notes of Forty Cases. J. Inglis Parsons.—Four years have elapsed since this author first adopted the operation here described. It does not interfere with pregnancy; the general idea is to strengthen the bands within the broad ligaments and enable them to hold the uterus up. The principle of treatment is very simple. It consists of taking advantage of Nature's reparative powers. The idea is simply to furnish a stimulus for the formation of lymph which repairs the ligaments when a joint is dislocated, and after thinking the subject over he decided to try this in uterine prolapse, to help Nature to repair the overstrained broad ligaments. The choice of re-agents requires consideration; it should be aseptic, the effect should be entirely local, and any absorption that takes place should be harmless. Sulphate of quinin most nearly fills all these conditions. When injected into the cellular tissue of the arm it appears to be precipitated and causes an effusion of lymph which remains for some weeks. It is also aseptic, and is a tonic to the general system if absorption occurs. A solution of this is injected into the cellular tissue of the broad ligaments from the vagina. The uterine arteries and veins lying on the inner side of the broad ligament are not in the way if the needle is inserted at the right point, as also holds true of the ureters, while the outer two-thirds of the lower half of the broad ligament contains no veins or arteries of any size or importance, and can be freely laid open from the vagina without having to tie a single vessel. The operation takes only a few minutes, and is not risky if performed with precision, proper care and antiseptic precautions. There is no rise of temperature as a rule. It is essential that the point of the needle should be within the folds of the ligaments and within the cellular tissue. An anesthetic is of advantage, though not absolutely necessary. The patient is placed in the lithotomy position and the parts aseptically prepared, the rectum, of course, having been emptied as well as the bladder. The posterior wall of the vagina is pressed down with a Sim's speculum, while the anterior is held up by a retractor. If they roll together in folds and block the view of the cervix two lateral retractors may be required. The injection is made with a thin, long, straight, rigid nozzle syringe and a needle about one inch in length and rather thicker than a hypodermic, and is passed on each side through the vaginal wall, taking care the direction of the needle is perpendicular to the base of the broad ligament and parallel to the long axis of the uterus. The needle should always be tested as the quinin solution corrodes it and it may then snap off. Some pain is felt after the injection, varying in different individuals. When the patient is lifted into bed the uterus should be well anteverted bimanually. A cup and stem india-rubber pessary secured by bands around the waist is inserted to keep the uterus well up until effusion of lymph has taken place. It will then be removed, as the uterus at the end of four or five days is held up by the effusion. The strength of the solution should be attended to. If too strong it will cause suppuration, or if too weak will not be sufficiently stimulating. For the past twelve months he has used a solution of 1 in 5, and the average amount inserted is 30 to 45 minims on each side. The temperature usually re-

mains normal. There may be a slight aching in the pelvis for a few days. It does not follow that one injection is sufficient, the condition of the parts, weight of the uterus, duration of prolapse and labor afterward will have to be considered. None of his patients have ever had the least signs of cinchonism, though in most instances as much as 12 grains have been injected at one sitting. He tries to keep his patients at rest after the operation for a certain time as much as possible. Of the 40 cases that he has operated on and which he tabulates, only 2 have relapsed, 4 have been only improved, while the other 34 patients have remained well.

Presse Medicale (Paris), September 18.

Ocular Disturbances or Deformities in the Insane. M. De Montyel.—Mignot found that only 19.5 per cent. of 82 insane persons he examined had normal eyes, and that in 41.4 per cent. a deformity of the pupil coincided with some ocular disturbance. In the present communication, the results of the examination of 77 insane subjects showed that only 16.8 per cent. were normal in this respect. The pupils were unequal in 37.7 per cent. In certain subjects the ocular deformity and disturbances were very pronounced, but in the majority they were slight.

Revue Hebd. de Laryngologie (Bordeaux), September 21.

Ozena in Sinusitis. J. E. Torrent.—In five cases of sinusitis, the clinical symptoms of ozena were presented in a pronounced form but they all vanished as the sinusitis yielded to treatment. Torrent believes that true ozena is a morbid entity, rebellious to treatment, but that all the symptoms can accompany an ordinary sinusitis and simulate true ozena, unless the actual cause is discovered in the sinusitis.

Syphilitic Peripheral Paralysis of the Muscles of the Pharynx. Charles.—A hitherto healthy child of 3, with apparently healthy parents, manifested symptoms of pharyngeal paralysis, such as are usually attributed to a known or unnoticed diphtheria. In the absence of any probable source of diphtheritic infection, Charles instituted specific treatment, with the cure of all the symptoms in twelve days. The father confessed later that he had a "disease with pustules" before marriage.

September 28.

Lithiasis of the Submaxillary Gland. Lafarelle.—The pains caused by the presence of calculi in the submaxillary gland are frequently ascribed to the throat and ear, as they radiate in all directions. Two cases are described, one in a woman of 40, the other in a man of 45. Besides the functional and physical signs of salivary lithiasis, the paroxysmal pains, the alternating swelling and subsiding of a submaxillary tumor, the discharge of purulent saliva from the tumor on compression and palpation of a hard substance, the complete permeability of Wharton's duct for the catheter indicated the location of the trouble. The preferable operation is the systematic extirpation of the submaxillary gland, as the acute inflammation caused by the calculi is certain to be followed by sclerosis of the gland. Even if the inflammation is slight, the gland should be removed to prevent recurrence. The operation is simple and easy. The facial vein has to be severed, but the facial artery and the hypoglossus nerve are left intact. The insignificant scar is hidden by the lower jaw.

Varices of the Base of the Tongue as a Sign of Cancer of the Esophagus. Lefrancois.—Painful varices at the base of the tongue were the only lesions discoverable in three patients who complained of dysphagia. Each one died within a year from cancer of the esophagus. Lefrancois queries whether the varices may not have been the first clinical symptom of the cancer below, or whether their presence was a mere coincidence.

Semaine Medicale (Paris), September 25.

Syringomyelia of the Medulla and Pons. Raymond.—In the case described, motor paralysis of all the limbs, with spasmodic paralysis of the legs, dissociated sensibility and kyphoscoliosis coincided with other symptoms which indicated a lesion in the medulla, atrophy of the left half of the tongue, neuro-paralytic keratitis of the left eye, lateral nystagmus and anesthesia of the left trifacial nerve and of the mucosa of the back of the throat. Raymond's pupils have been studying the lesions in the autopsies of cases of syringomyelia during the last six years. They have found that the first lesion occurs in the region around the ependyma, near the central canal of the spinal cord, gradually invading the posterior cornu, the base of the anterior cornu and the adjacent portions of the white tracts. The lesion may range from an insignificant fissure with compact walls to an immense cavity involving all the elements of the cord and medulla. The spinal meninges may or may not be affected. Microscopic sections have fully demonstrated the inconstant relation of the syringomyelic gliosis with the central canal, and its special fissure-forming development. It is evident that certain cases of hypertrophic cervical pachymeningitis, but not all, belong in the domain of syringomyelia. Syringomyelia is, therefore, a definite affection like sclerosis in plaques. Its essence is a specific gliosis, produced independently of any other pre-existing lesion or affection of the spinal cord, such as myelitis or sclerosis, by the proliferation of the neuroglia in response to multiple pathogenic causes. This gliosis is to be distinguished from glioma and from cavity-forming myelitis. The syringomyelic lesion may spread laterally or longitudinally and consequently may affect the most varied anatomic and functional systems, inducing equally variable associations of symptoms. It may simulate more or less deceptively almost any one or all of the affections due to disease of the spinal cord or medulla, from progressive muscular atrophy to tabes and leprosy. But there is always a fourfold group of morbid phenomena more or less evident in syringomyelia: trophic disturbances, dissociated superficial sensibility and a tendency to scoliosis and paralytic motor troubles. The lesions are incurable, but as long as they are restricted to the spinal cord, long survival is possible. When the symptoms indicate that the medulla and pons have been invaded, a rapidly fatal termination is inevitable.

Simultaneous Appearance of Mosquitoes and Malaria. A. Billet.—This communication from Algeria states that a careful watch was kept for the first appearance of anopheles, to determine if it coincided with the first cases of malaria. The mosquitoes began to arrive June 15, and between June 26 and July 10, seven soldiers who had arrived during the winter, were received at the hospital affected with malarial fever, the first malarial patients of the year.

Two Cases of Actinomycosis in the Parametrium. C. Fehmers.—A woman in good health and menstruating normally, noticed pains in the right half of the abdomen and discovered a tumor. Three weeks later she entered the hospital and, with a diagnosis of pelvic peritonitis, the posterior cul-de-sac was incised and drained. The patient was much relieved but returned a month later on account of a lumbar abscess communicating with the initial pelvic focus. Actinomyces were found in the pus, and iodin treatment was commenced. A series of abscesses formed in the lumbar region and abdominal walls, with a stercoral fistula. After eighteen months of treatment, the patient seemed to be practically cured, although the fistula still persisted. She returned a year later with recurrence of severe symptoms, and died in collapse during the laparotomy. The intestines and uterus were found solidly fixed and altered by the lesions and adhesions. The patient had had one pregnancy years before. In the second case, the patient was a multipara, with abundant and prolonged menstruation. During a convalescence from typhoid fever, a sudden pain attracted attention to the right hypogastrium and a tumor was discovered, assumed to be a suppurating ovarian cyst. At the laparotomy the tissues were found much infiltrated and a focus of pus containing actinomyces was discovered. Vigorous local and general iodin treatment was instituted, and the patient seems to be completely recovered. The cases are reported in detail in the *Nederl. Tijdschr. v. Geneesk.* of June 29.

Deutsche Med. Wochenschrift, October 3.

Treatment of Anthrax. F. Schultze.—Strubell described last year a case of malignant pustule just below the eye, which he cured by the application of hot compresses, renewed every ten minutes, night and day, supplemented by injections of 12 c.c. of a 3 per cent. solution of carbolic acid. Schultze relates a similar case of malignant pustule also just below the eye. The treatment was restricted to the application of a sublimate 1 to 1000 dressing, in a 70 per cent. alcoholic solution over the ulcerating portions. Quinin was given in 30 cg. doses every three hours during the febrile period, and 30 cg. of naphthalin were administered occasionally on account of the diarrhea. The patient progressed even more rapidly to recovery than Strubell's patient, although the symptoms were if anything more serious. The intoxication is the chief danger in such cases, and it presents a clinical picture closely resembling that of typhoid fever, aside from the local phenomena. The bronchi and kidneys as well as the intestines were involved and the cerebral symptoms were the same as those observed in typhoid fever.

Electric Light Sweat Baths. Krebs.—As the results of experiences and observation at the hydrotherapeutic institution connected with the University of Berlin, Krebs announces that incandescent light baths induce profuse sweating more rapidly and at a lower temperature than is required for hot-air baths. This effect is probably due to the heat rays in these lights. The arc light is much less effective. Patients with organic heart defects may find these baths injurious.

Prognosis of Diabetes and Tuberculosis. G. Oeder.—It is usually supposed that tuberculosis in a diabetic subject runs an unusually rapid course. Oeder describes the case of a diabetic patient who has exhibited unmistakable symptoms of pulmonary tuberculosis for six years, but both diseases have seemed to be in *statu quo* for several years.

Monatsschrift f. Geb. u. Gyn. (Berlin), July.

Metastases in the Ovaries in Case of Primary Abdominal Malignant Disease Elsewhere. E. Kraus.—The 11 observations collected include 3 in which the primary carcinoma was located in the stomach, and 7 in the gall-bladder or biliary passages. The patients had been operated on for the easily diagnosed tumor in the ovaries, which was merely a metastasis of the small primary tumor elsewhere which had been completely overlooked. The slight symptoms on the part of the alimentary canal had been attributed to reflex irritation. The patients bore the ovariotomy well, but succumbed later to the gradual evolution of the primary tumor, which could easily have been removed at the same time if its presence had been suspected. Kraus urges search for a primary tumor when both ovaries form cancerous, knobby tumors, and section shows the characteristic peripheral arrangement of the tumor masses. If the ovaries are found even slightly enlarged and hard, during the extirpation of a primary neoplasm in any abdominal organ, they should be considered suspicious, especially if nodules are discovered in Douglas' pouch. He reports experiments which demonstrate that cancerous elements are able to penetrate into the intact ovary from its outer surface, even in the case of rabbits' ovaries, which are smaller and less exposed to danger of penetration than the human ovary.

August.

Stimulation of Labor by Intrauterine Rubber Bag. G. Hauffe.—The advantages of the rubber bags used by Hauffe are that when distended with fluid, they are comparatively hard, and prove an energetic stimulus to the contractions of the uterus, much more so than the soft bags ordinarily employed for this purpose.

September.

Diagnosis of a Vesicular Mole. W. Poten.—The diagnosis of a vesicular mole is sustained by the lack of elastic tension in the walls of the uterus, which feel like soft clay on palpation. There are also, in case of a vesicular mole, peculiar contractions of circumscribed portions of the uterine walls, occurring spasmodically and subsiding completely. In one case the uterus seemed to contain a hard myoma, the size of a fist, in an otherwise soft organ. Half an hour later, the supposed myoma had vanished to reappear again in another portion of the organ. The patient is not conscious of these contractions. In three cases described, the patients were in the sixth to the ninth month of pregnancy. In another case, the mole had ceased to proliferate, remained in the uterus like an inert foreign body and was finally expelled. In two other cases the symptoms had some analogy with those described, but a macerated fetus instead of a mole was found in each instance.

Heart Defects and Pregnancy. O. Fillner.—The prognosis of pregnancy in case of cardiac defect is not so serious as has been generally assumed, judging from the experiences at Schauta's clinic since 1892. They include 94 patients with 305 births, out of a total of 30,613 deliveries in the Maternity. Fillner has also collected 140 cases from the literature, with 520 births. The results show that with appropriate treatment the overwhelming majority of the patients pass through the stress of childbirth without any special disturbance or even a suspicion of their cardiac defect. Delivery is frequently longer than usual. In all cases of uncompensated cardiac defect a more or less extensive ring of necrosis is found at the edge of the placenta. The pregnancy was spontaneously interrupted in 20.2 per cent. of the cases, with a mortality of 25.5 per cent. for the children. Only a very small percentage succumbed to the heart trouble; 6.3 per cent. at Schauta's clinic and .9 per cent. of all those systematically investigated. Mitral stenosis alone seems to afford an unfavorable prognosis. In other conditions, it is not the kind, but the extent of the defect which is the decisive element. Only in the rarest cases is any unfavorable influence on the heart defect from the pregnancy to be discovered. In case of compensated defect, premature delivery is not indicated unless the patient was in peril of death in previous childbirths. In case of uncompensated defect premature delivery is indicated only when treatment has no chance of success; otherwise internal treatment should be applied first and after improvement has been obtained, the pregnancy should be artificially interrupted. Mitral stenosis, and the complication of a cardiac defect by chronic nephritis or tuberculosis, require more vigorous procedures. In case of compensated defect, the bougie alone should be used. If a fatal termination is imminent, the fetal membranes should be ruptured which will give temporary relief, and may prove useful in case of edema of the lungs. It is better not to wait too long before applying the forceps in case of an uncompensated cardiac defect. Marriage need be forbidden only in case of pronounced disturbances in compensation, or mitral stenosis or a defect complicated by tuberculosis and chronic nephritis. If severe disturbances in compensation appear during the course of a pregnancy, future pregnancies should be forbidden, and in case of deadly peril during a pregnancy, the patient should be rendered sterile.

Muenchener Med. Wochenschrift, September 24.

Senile Pruritus of the Tongue. E. Baumgarten.—During the last three years Baumgarten has had occasion to observe two cases of pruritus of the tongue, occurring in elderly women, with all the characteristics of senile pruritus of the skin, and in one case followed later by cutaneous manifestations. A long array of remedies was tried, but without avail; the pruritus persisting unaffected. Some local or general cause can usually be found for tongue troubles and the diagnosis of senile pruritus should not be made until after the exclusion of affections of the stomach or intestines, constipation or other general cause, including the dry catarrh of the throat which is a frequent companion of the menopause, and usually coincides with dryness, smarting and burning sensations in the tongue. The latter may also occur in cases of disturbed menstruation. Pure neuralgia of the tongue is extremely rare, but neurasthenic disturbances involving the tongue are not infrequent in both men and women. In three cases Baumgarten diagnosed

tabes from the pains in the tongue alone, confirmed by the later course of the disease. Pains and smarting of the tongue, especially when accompanied by ptyalism, are very suspicious of commencing paralysis. In other cases, the symptoms noticed in the tongue were the precursors of some local affection. Varices of the base of the tongue are cauterized by some physicians, but this is useless unless the general cause inducing them is removed.

Lysol Intoxication. G. Burgl.—Two cases are related in which pure lysol was administered to a child by mistake, and eighteen cases of lysol intoxication in the literature are reviewed. They show that prompt use of the stomach pump was followed by the recovery of all the patients thus treated, while the neglect of this measure was almost invariably fatal. The solution should never be stronger than 1 per cent. for external application and .5 per cent. for irrigating internal cavities. It should never be used long at a time. One death has been known from the external application of pure lysol on the intact skin. If it is administered internally, the minimal dose should be taken as the standard, and it should never be given except for a brief period and better not at all, in case of children or feeble patients. In the 18 cases collected, the intoxication occurred in 13 from internal and in 5 from external use of the agent. Nine of the patients died, 5 children and one adult after internal administration, and 2 adults and one child after the application of pure lysol externally, by mistake for the 1 per cent. solution that had been ordered. The largest dose from which the patient recovered was 60 gm., taken by a woman, and 25 gm. by a 4-year-old child. The smallest dose that proved fatal was a teaspoonful, about 4 to 5 gm. of pure lysol, in children from 5 days to 8 years old.

Tamponing the Abdominal Cavity with Air to Arrest Threatening Hemorrhage. G. Kelling.—A series of experiments on dogs and cadavers are described, showing the harmlessness of this measure and its efficacy in arresting threatening internal hemorrhage. The accumulations of ascitic fluid in the abdomen prove that it will tolerate considerable stretching. Tests on seven cadavers of adults between 37 and 87, demonstrated that the abdomen could be thus inflated to a pressure of 150 mm. mercury or 1.5 meter water without laceration of the peritoneum. The apparatus consists of a T-shaped glass tube connected by a rubber tube with the mercury column at one end: with a double rubber air bulb at the other, and with the puncturing needle on the third branch. The tube connecting with the needle is interrupted by two bottle-shaped bottomless glass tubes, connected by a short rubber tube. The broad part of these bottle-shaped tubes is loosely packed with cotton to filter the air. It is injected under close supervision of the respiration and heart action, until a negative pressure of 30 mm. mercury or, better still, of 50 mm. is obtained. The stomach, bladder and rectum are liable to evacuate their contents by the mechanical effect of the pressure, for which preparations must be made. In case of hemorrhage of the stomach, some substance to promote coagulation should be administered by the mouth before injecting the air. After numerous tests, Kelling found pulverized chalk mixed with milk, the most effective local measure for this purpose. It can be administered by the mouth in not too small amounts. He has never had an opportunity to apply this tamponing measure in the clinic, but his tests on large dogs have been so successful that he is confident it will prove extremely useful in practical application to patients. He warns that the subjective sensations are no criterion, but that the circulation and pulse must be carefully watched. The first part of his report was published in The Journal of October 12, p. 1010.

Brazil-Medico (Rio de Janeiro), September 1.

Death After Spinal Tropa Cocainization. D. de Almeida. The patient in the case reported was 80 years of age, and had eaten nothing for three or four days. The operation was undertaken for the relief of incarcerated inguinal hernia, and 2 cg. of tropacocain were injected in the subarachnoid space, in a 2 per cent. solution. A few minutes after the operation had been completed, the pulsations of the heart gradually grew less and less perceptible, and the patient died with no other symptoms except this quiet failing of the heart action.

Proofs in Favor of the Transmission of Yellow Fever by Mosquitoes. E. M. Ribas.—The superintendent of the board of health at Sao Paulo, Dr. Ribas, is convinced of the plausibility of the mosquito theory and suggests that mosquitoes may bite during the hours of early morning, while the subjects are still sleeping, as the culex teniatus is not a night insect. He describes a convincing incident in the outbreak of yellow fever at Sao Paulo in 1900. No cases had been known in town for a long time, when an Italian ship arrived from Rio, January 2, and one of the crew suffering from yellow fever was received in the hospital. Fourteen days later, five other yellow-fever patients were admitted. All were sailors from two vessels moored along the quays near the Italian ship. The culex teniatus is found in the street that fronts the quays, and the row of ships formed as it were, a row of dwellings on the seaward side of the street, where the culex could easily penetrate. Other sailors were affected soon afterward; all being men who had lived a number of months in the town without previous infection. The epidemic was arrested after it had attacked 490 out of the 50,000 inhabitants of the town. The sanitary measures applied in the infected ships and dwellings probably destroyed the infected mosquitoes, and thus contributed to the arrest of the epidemic.

Cirugia Contemporanea (Mexico), September 15.

Intra-Arachnoid Cocainization in Mexico. R. Norma.—Eighty-seven operations have been reported in Mexico, done under spinal cocainization. No threatening by-effects were noted in any case; in 31 no symptoms of any kind were observed, in 32 the usual slight headache, vomiting or nausea. In one case an overdose was used, with the symptoms to be anticipated in such a case. In two other cases, one a hysteric and one a much debilitated hemiplegic, the temperature rose to 104 F. in one, and syncope occurred in the other. Norma considers that the simplicity and prompt efficacy of this method of surgical analgesia commend it particularly for alcoholic subjects.

Cronica Medica Mexicana (Mexico), October 1.

Mercury for Injection Into Vessels for Radiography. D. Garcia.—Mercury answers all the conditions required to render even the most delicate macroscopic capillaries visible in radiography. Garcia has devised an apparatus for the purpose, a glass canula with two stopcocks and graduated receptacle, which enables the injection to proceed without admixture of air. Radiographs of anatomic specimens thus prepared were remarkable for the wealth of details, as even a thickness of one-tenth of a millimeter casts a clear shadow.

Value of Ferric Chlorid in Therapeutics. J. B. Hernandez.—The remarkable anticongestive, antiphlogistic, antisuppurative and anti-exudative action of ferric chlorid is proclaimed by Hernandez. He considers it superior to all other substances for the treatment of superficial inflammatory or catarrhal lesions. It is ineffective in profound inflammation and actually injurious in chronic inflammation But it has proved remarkably beneficial in his experience in erysipelas, phlegmons, smallpox, eczema, herpes zoster, and catarrh of the vagina, cervix and conjunctiva. It is also valuable in acne rosacea, anthrax, hemorrhoids, gastritis, otitis, rhinitis, rectitis, gonorrhea and catarrhal metritis of the fundus. He uses the chlorid in "Pravaz's solution," and appends to this communication numerous case—reports to substantiate his statements.

Cronica Medica (Lima), xvii, 301 and 302.

Causal Agent of Verrugas Peruana. A. L. Barton.—The researches of three years have been crowned with success, Barton announces, by the discovery of the bacillus derived from the spleen, blood and mesenteric ganglia of patients suffering from verrugas. Inoculated into animals it produces the typical symptoms of the clinical disease. It is extremely motile, stains readily, is not pyogenic, and is more pathogenic for the mule than for the dog, the only animals experimented on.

Queries and Minor Notes.

TEACHING OF PHYSICAL THERAPEUTICS.

PHILADELPHIA, Oct. 8, 1901.

To the Editor:—In an editorial in THE JOURNAL of Oct. 5, 1901, p. 916, you refer to the subject of the "teaching of physical therapeutics," and state that there are at present being published in English and German, systems of therapeutics in which physical agents especially are discussed. I shall be under many obligations to you if you will kindly indicate the publications to which you refer, because I am very much interested in this subject and desire all the information with regard to publications obtainable.

B. H. D.

ANS.—P. Blakiston's Son & Co. are publishing a "System of Physiologic Therapeutics," edited by Dr. S. Solls-Cohen; there is in process of publication a "Handbuch der Physikalischen Therapie," edited by Goldscheider and Jacob (George Thieme, Leipsic). Further, there is a German periodical, *Zeitschrift für diätetische und physikalische Therapie*, edited by Leyden and Goldscheider, and there is also published in Great Britain a *Journal for Physiological* (or Physical) *Therapeutics*.

AKOUPHONE.

CONCORDIA, KAN., Sept. 18, 1901.

To the Editor:—In THE JOURNAL of April 6, 1901, p. 982, is a description of the akouphone and akoulalion by J. R. Hutchinson, before the New York Academy of Medicine. Can you give me the address of the manufacturer? I have a child I desire to try one on.

W. F. S.

ANS.—Address the Akouphone Company, 43 E. 20th St., New York City.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., October 3 to 9, inclusive:

William J. Calvert, lieutenant and asst.-surgeon, U. S. A., leave of absence granted.

W. Fitzhugh Carter, major and surgeon, U. S. A., will accompany the Third Battalion of Engineers to Washington Barracks, D. C., and thereafter return to his proper station, Fort Totten, N. Y.

Max F. Clausius, contract surgeon, previous orders directing him to proceed to his home for annulment of contract, revoked.

John Ryan Devereux, lieutenant and asst.-surgeon, U. S. A., from duty at Washington Barracks, D. C., via Tampa, Fla., to Havana, Cuba, for assignment in the Department of Cuba.

Clyde S. Ford, lieutenant and asst-surgeon, U. S. A., former orders directing him to proceed to Fort Morgan, Ala., revoked; he will repair to Washington, D. C., and report to the Surgeon-General for instructions.

Joseph H. Ford, lieutenant and asst.-surgeon, U. S. A., from Fort Washington, Md., to duty at Washington Barracks, D. C.

Myer Herman, captain and asst.-surgeon, Vols., having tendered his resignation, is honorably discharged from the service of the United States, to date from October 8, 1901.

James H. Holloway, contract surgeon, leave of absence extended.

William L. Kneedler, major and surgeon, U. S. A., leave of absence granted.

Conrad E. Koerper, lieutenant and asst.-surgeon, U. S. A., now on duty at the General Hospital, Washington Barracks, D. C., to report for temporary duty to the commanding officer of that post.

Clarence B. Millhoff, lieutenant and asst.-surgeon, U. S. A., leave of absence extended.

Arthur W. Morse, lieutenant and asst.-surgeon, U. S. A., from the U. S. General Hospital, Presidio of San Francisco, Cal., to post duty at Fort Walla Walla, Wash.

Edward L. Munson, captain and asst.-surgeon, U. S. A., will, on the completion of his present duty at the Pan-American Exposition, Buffalo, N. Y., repair to Washington, D. C., for duty in the office of the Surgeon-General.

Junius L. Powell, major and surgeon, U. S. A., is relieved from further duty in the Division of the Philippines and assigned to post duty at Fort Hamilton, N. Y.

Frederick F. Russell, lieutenant and asst.-surgeon, U. S. A., now in New York City, will proceed to Fort Washington, Md., for post duty.

Paul S. Shillock, major and surgeon, U. S. A., leave of absence granted.

Herbert M. Smith, lieutenant and asst.-surgeon, U. S. A., recently appointed, from Salem to Fort Monroe, Va., for temporary duty.

W. Manley Waterhouse, contract surgeon, former orders relieving him from further duty on the transport *Logan*, and from temporary duty at the General Hospital, Presidio of San Francisco, Cal., and directing him to proceed to Fort Grant, Ariz., for post duty, revoked.

Navy Changes.

Changes in the Medical Corps of the Navy, week ending Oct. 12, 1901:

Surgeon L. L. Von Wedekind, detached from the Puget Sound Naval Station and ordered home and to wait orders.

Surgeon O. D. Norton, detached from the *Monadnock*, on reporting of relief, and ordered home and to wait orders.

P. A. Surgeon D. H. Morgan, ordered to the *Philadelphia*.

P. A. Surgeon A. W. Dunbar, detached from the Naval Hospital, Mare Island, Cal., and ordered to the Puget Sound Naval Station.

P. A. Surgeon S. G. Evans, detached from the *Solace*, upon reporting of relief, and ordered home and to wait orders.

P. A. Surgeon A. R. Alfred, detached from the Marine Barracks, Cavite, P. I., and ordered to the *Monadnock*.

P. A. Surgeon J. M. Moore, detached from the *Franklin*, upon reporting of relief, and ordered to the *Indiana*.

Asst.-Surgeon C. G. Smith, detached from the *Alvarado* and ordered to the *Marietta*.

Asst.-Surgeon F. E. McCullough, detached from the *Philadelphia* and ordered to the Naval Hospital, Mare Island, Cal.

Asst.-Surgeon J. F. Murphy, detached from the *Indiana*, upon reporting of relief, and ordered to the *Solace* for temporary duty, and then to the Marine Barracks, Cavite Naval Station.

Asst.-Surgeon W. H. Bell, ordered to the *Franklin*.

Asst.-Surgeon D. G. Beebe, detached from the *Marietta*, upon reporting of relief, and ordered home to wait orders.

Asst.-Surgeons A. M. Fauntleroy and L. W. Bishop, commissioned assistant-surgeons from Sept. 28, 1901.

Surgeon C. F. Stokes, detached from the *Oregon* and ordered to the *Solace*.

Surgeon G. A. Lung, detached from the Marine Barracks, Cavite Naval Station, on reporting of relief, and ordered home and to wait orders.

Surgeon L. W. Spratling, commissioned surgeon from Sept. 28, 1901; detached from the Naval Hospital, Cavite, P. I., on reporting of relief, and ordered home and to wait orders.

P. A. Surgeon M. S. Guest, detached from the Naval Hospital, Philadelphia, Pa., and ordered to the *Solace*, for temporary duty, and ordered to the Cavite Naval Station, on arrival at the Asiatic Station.

P. A. Surgeon A. Farenholt, ordered to the *Independence*.

P. A. Surgeon M. K. Johnson, detached from duty at Guam, on reporting of relief, and ordered to the Marine Barracks, Cavite Naval Station.

Asst.-Surgeon C. D. Langhorne, ordered to the Naval Hospital, Naval Home, Philadelphia, Pa.

Asst.-Surgeon W. Seaman, detached from the *Independence*, on reporting of relief, and ordered to the *Solace* for temporary duty, and ordered to duty at Guam, on arrival at that place.

Asst.-Surgeon H. M. Tolfree, detached from the *Columbia* and ordered to the *Solace* for temporary duty, and ordered to duty at Guam, on arrival at that place.

Asst.-Surgeon J. B. Dennis, detached from the Naval Academy and ordered to the Naval Hospital, New York.

Asst.-Surgeon R. M. Young, detached from the New York Navy Yard and ordered to the *Columbia*.

Asst.-Surgeon R. M. Fauntleroy, ordered to the Naval Academy.

Asst.-Surgeon J. J. Snyder, detached from duty at Poloc, P. I., and ordered to the Naval Hospital, Cavite, P. I., for treatment.

P. A. Surgeon J. A. Guthrie, detached from the *New York* and ordered to duty at Port Isabella, P. I.

Asst.-Surgeon R. K. McClanahan, detached from duty at Port Isabella, P. I., and ordered to duty at Poloc, P. I.

Asst.-Surgeon F. A. Asserson, detached from the *General Alava* and ordered to the *New York*.

Asst.-Surgeon F. L. Benton, detached from the *Brooklyn* and ordered home.

Health Reports.

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Oct. 5, 1901:

SMALLPOX—UNITED STATES.

Alaska: Dawson, Oct. 1, 6 cases.
District of Columbia: Washington, Sept. 28-Oct. 5, 1 case.
Indiana: Michigan City, Sept. 30-Oct. 7, 1 case.
Massachusetts: Sept. 30-Oct. 5, Boston, 9 cases, 1 death: Newton, 1 case.
Michigan: Detroit, Sept. 30-Oct. 5, 1 case.
Minnesota: Minneapolis, Sept 30-Oct. 5, 1 case.
Nebraska: Omaha, Sept. 30-Oct. 5, 2 cases.
New Jersey: Newark, Sept. 30-Oct. 5, 2 cases, 2 deaths.
New York: Sept. 30-Oct. 5, Elmira, 1 case; New York, 7 cases, 2 deaths.
Ohio: Cleveland, Sept. 30-Oct. 5, 4 cases.
Pennsylvania: Erie, Sept. 21-28, 2 cases; Philadelphia, Sept. 30-Oct. 5, 40 cases, 6 deaths.
Utah: Salt Lake City, Sept. 30-Oct. 5, 2 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Sept. 7-14, 1 case.
Belgium: Sept. 14-21, Antwerp, 5 cases, 1 death; Ghent, 1 death.
Brazil: Pernambuco, Aug. 15-31, 73 deaths; Rio de Janeiro, Aug. 18-Sept. 1, 115 deaths.
Canada: Halifax, Sept. 22-Oct. 5, 20 cases; Winnipeg, Sept. 14-21, 1 case.
Colombia: Colon, Sept. 30, epidemic.
France: Paris, Sept. 7-14, 2 cases.
Great Britain: Dundee, Sept. 14-28, 2 cases; London, Sept. 14-21, 288 cases, 13 deaths.
India: Bombay, Sept. 3-10, 1 death; Calcutta, Aug. 24-Sept. 7, 4 deaths; Madras, Aug. 24-Sept. 6, 8 deaths.
Mexico: City of Mexico, Sept. 15-22, 1 case.

PLAGUE—FOREIGN.

Philippine Islands: Manila, Aug. 10-24, 15 cases.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Aug. 18-Sept. 1, 5 deaths.
India: Bombay, Sept. 3-10, 275 deaths; Calcutta, Aug. 24-Sept. 7, 34 deaths; Karachi, Aug. 25-Sept. 8, 35 cases, 11 deaths.

YELLOW FEVER.

PROSTATECTOMY, THE METHOD OF CHOICE IN THE MANAGEMENT OF PROSTATIC OBSTRUCTION.*

EUGENE FULLER, M.D.

Professor of Genito-urinary and Venereal Surgery at the New York Post-Graduate Medical School; Visiting Genito-urinary Surgeon to the City Hospital, Etc.

NEW YORK CITY.

Prostatic hypertrophy, directly or indirectly, is the cause of death in such a large proportion of elderly men that the question of its surgical management is one of the greatest importance. In the case of most individuals who so die at the present time no serious attempt is made to save life. The community at large is not as yet educated beyond the idea of the catheter, and the same, I am sorry to say, can almost be said of the medical profession. A few years ago a person could die of appendicitis in the absence of surgical treatment and no adverse comment would be provoked by the event. Now, however, such a happening is regarded by the sensible portion of the community much as is the death of a person under faith-cure treatment, and no physician who is careful of his reputation fails at least to raise the question of surgical interference in cases of this latter description.

It is not to be expected that resort to radical surgery will ever become as general in the case of prostatic obstruction as in that of appendicitis, since the former disease is consequent to advanced life and the other is not.

The question of senility is the one to be prominently considered in connection with prostatic surgery. Upon it is based the chief and often violent opposition of those related to or standing sponsor for the patient. In weighing opposition of that character I am very apt to recall what a very bright and elderly gentleman once told me in commenting on the proper limit of life. He said: "It is not desirable to live to too great an age. If an old man is without means, those on whom he is dependent after a time grow tired and are then satisfied when he dies. If, on the other hand, he has means, then those waiting to inherit become impatient if life is too long prolonged." Pure love and devotion is without doubt the cause for such opposition in most cases, I am glad to say; still, many times one is compelled to observe the truth of these somewhat cynical remarks. The younger, of course, a patient is the better. The question of operation is, however, rarely raised before the age of 57 to 60. When a patient is under 65 I look upon him as young in connection with prostatic surgery, and when between 65 and 72, as middle-aged. Formerly I was inclined to put 75 as an extreme limit and to rather advise against operation and in favor of a do-nothing policy had a patient passed that age. Finding, however, that my results were good right up to that limit, I have raised it. During the last year I have gotten two strikingly good results, one in a man of 78 and the other in a man of 77. Aside from their ages these individuals were both apparently very bad surgical risks. The man of 78 was bedridden. He had a suprapubic vesical fistula and putrid urine. He was moderately emaciated, the effect of pyrexia occasioned by the absorption of bacterial urine. The fistula was the result of a suprapubic cystotomy undertaken in the vain hope that some relief might follow its establishment. The individual of 77 represented a case of surgical emergency for the relief of extreme and constant vesical tenesmus unrelieved by opiates pushed as far as seemed judicious. The lesion in this case was a large obstructive prostate, which was undergoing peripheral suppuration, and a resulting phosphatic calculus nearly 3 ounces in weight. The individual at the time of operation was mentally excited and somewhat irrational, which I took to be a symptom of uremia, although it is possible that the opium may have been to a greater or less degree a causative factor.

A surgeon should always be influenced by age. A man of 60 or thereabouts is in a different position from a man of 75 or over. The former individual can naturally hope for a much longer lease, not only of life, but also of its attendant enjoyments than can the latter. Men in their sixties are often the most valuable members of society. The surgical question with individuals of that class is not only to prolong life, but to save them from invalidism, keeping them bodily vigorous so that not only can they enjoy their advancing life, but their families and the public can also profit by their wisdom, protection and experience. Consequently with them, even though a surgical emergency has not arisen, operation should be advised. In those of 75 or thereabouts, if sufficient relief attends the use of the catheter so that life is reasonably bearable, radical operation should perhaps only be urged if there be good reason to suppose that the catheter will in the near future fail to relieve suffering and avert death. In a case of emergency a prompt resort to radical surgery should be employed, not only to save life, but to relieve suffering, so that if death must occur it will at least be placid.

Aside from the question of age, the surgeon in considering operation should be guided by the physical and mental condition of the individual. The existence of arterio-fibro-sclerosis can be mentioned as a decidedly unfavorable condition, since chronic interstitial nephritis always coexists. Calcareous infiltration into the walls of the blood vessels is a bad, but not contraindi-

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker, and A. J. Ochsner.

cating, feature. History of antecedent dissipation, the existence of pulmonary, cardiac and other defects, should be weighed as unfavorable factors, just as before any surgical operation. Putrid urine and the presence of an ascending pyelitis, together with some involvement of the kidney, should not be made to stand in the way of operation, but their existence should strengthen the plea for speedy relief from prostatic obstruction, the direct cause for their presence and continuance. Where such infective processes exist, uremia and death will finally result from their progression, so it may be in a given instance that operation has been too long delayed and that death is thereby to a slight degree hastened. In very many such instances, however, where the infective complication appears extensive and serious, radical operation is followed by a perfect recovery.

The decision having been made to resort to radical relief from prostatic obstruction, the next question that arises is how to accomplish that relief. In the majority of cases that come to my notice there is no occasion for debate on that point, the question of procedure having resolved itself into that of prostatectomy or nothing, unless it be the establishment of a permanent suprapubic vesical fistula, a surgical makeshift that no progressive genito-urinary surgeon at present is apt to employ except in case of malignant disease. Some may take exception to this statement, and to such I explain that many times cases do not come to my notice until an emergency has arisen, an expert opinion being then for the first time sought.

In the minority of cases it may be proper in connection with the question of prostatectomy to consider the advisability of castration or of the Bottini operation as substitute measures.

The cases demanding prostatectomy and in which that operation alone will suffice, can be grouped as follows: 1, those not amenable to urethral instrumentation; 2, those demanding vesical or perineal drainage as well as relief from prostatic obstruction; 3, those in which renal infection exists as a complication; 4, all those complicated by phosphatic calculi in which litholopaxy is impracticable; 5, those in which the prostatic mass causing obstruction is such as to require direct removal, not being amenable to less radical surgical treatment.

By cases not amenable to urethral instrumentation are meant those demanding prompt relief from prostatic obstruction and in which some serious impediment to the passage of an instrument exists. Narrow meatus, soft or linear stricture of the penile urethra, or soft stricture of the deep urethra, are difficulties which can be easily overcome and consequently are not to be reckoned in this connection. Deep unyielding stricture or false passage are the urethral conditions which usually interfere. Not infrequently the anterior face of the prostatic hypertrophy juts so prominently into the urethral space as to make the passage of any catheter, except perhaps a metallic one with an extreme curve, impossible or uncertain. Oftentimes in cases of prostatic retention the membranous urethra is severely lacerated through unskilful and violent attempts at cathetherization, a result which may make a subsequent passage of the instrument in competent hands impossible or so difficult as to be very injurious to the patient.

In many instances where a bladder, before it finally succumbs, has struggled successfully for a long period to overcome the resistance offered by an increasing prostatic obstruction, marked vesical lesions are developed, which require for their cure and the restoration of the vesical function not only the removal of the prostatic obstruction, but vesical rest as well, which latter factor can not be obtained except through a combined cystotomy. Severe inflammatory lesions of the bladder, the result of chronic cystitis dependent on prostatic obstruction, often demand direct vesical drainage and rest for their resolution aside from the removal of the existing cause. Periprostatic suppuration and perineal phlegmon due to lesions of the prostatic urethra resulting from constant catheterization require perineal drainage.

Where renal infection exists in this class of cases it is, of course, of an ascending variety. The chief agency in accomplishing its elimination lies in extreme and unobstructive diuresis, which can only be attained by thoroughly draining the bladder.

The reason for the necessity of prostatectomy in cases complicated by prostatic calculi which lie in the postprostatic cul-de-sac, out of the reach of the lithotrite, is evident without further comment.

Cases in which the prostatic mass causing obstruction is such as to require direct removal are those in which the mass is large, in which it projects extensively into the intravesical space, and in which its intravesical contour is decidedly irregular. In other words, it might be said that all cases of prostatic obstruction accompanied by a surgical emergency aside from that of simple retention, and all cases at all complicated or associated by complications are suitable for prostatectomy and that only, while as regards the easier and selected cases other surgical methods might perhaps be tried.

In making mention even of castration as a surgical method for the removal of prostatic obstruction many would be apt to criticise me on the ground that the procedure is now out of date, having been discarded by the profession. I think such criticism very likely justifiable. I do not myself remove the testicles for that purpose. I have seen a few well-authenticated cases wherein relief from the obstruction has followed that operation. Most of the cases which I have seen were, however, not relieved, but subsequently submitted to prostatectomy at my hands. I will not discuss the operation further in this connection. With the sudden subsidence of the operation just mentioned the procedure advocated by Bottini has again been brought to notice through the modification of the original operation adopted by Freudenberg and at the present time is receiving considerable attention. As Freudenberg's procedure is fairly well understood by the profession, no attempt will here be made to describe it. It has one great advantage in common with castration: It is easy of accomplishment, anyone who is at all familiar with the manipulation of urethral instruments being able to properly execute it. In that respect, and in that chiefly, to my mind, has it an advantage over prostatectomy. Owing to its ease of accomplishment many more practice it than attempt prostatectomy. The idea conveyed by the operation is attractive and far more popular than that of castration. The avoidance of cutting appeals to many, as does also electricity, the agency to be employed. Some who practice the operation emphasize the fact in advocating it that the operation itself is in a large measure free from after-discomfort, besides requiring brief confinement in bed. Others advocate a confinement of three weeks or thereabouts, treating the

procedure as one of considerable surgical magnitude. The statistics coming to hand of this operation in its present modified form are certainly attractive, especially those of operators who are very careful in selecting their cases, trying the operation only on subjects to which it is apparently best adapted. Such statistics show a slight majority of cases relieved of symptoms, while in a fair percentage of the minority more or less relief of symptoms is noted. There is a great difference between a relief of symptoms and a radical cure. A relief of symptoms occurs when a patient is again able to urinate with sufficient freedom to no longer require the aid of a catheter or be distressed through the performance of the act. A radical cure signifies a complete restoration of the vesical function, which means a complete emptying of the bladder at the end of every act of urination. In most of the best results after the Bottini operation some, and often considerable, residual urine always remains. After convalescence from prostatectomy, certainly as I perform it, there is no residual urine. The term radical cure should never be applied to a prostatic operation which does not eliminate the element of residual urine. In a good percentage of cases, however, the Bottini operation fails to relieve. The mortality attending it appears to be in the neighborhood of 10 per cent., perhaps somewhat under. Medical statistics concerning a new procedure should always be put on the shelf a while for seasoning before being accepted. The statistics which first appeared in favor of castration for the relief of prostatic obstruction were, I think I am correct in saying, even better than those in favor of the Bottini operation, but subsequent surgeons could never verify them. The cases suited to this operation are those free from the complications already mentioned, in which the prostatic obstruction takes the form of a moderate-sized middle lobe or of an hypertrophy and rigidity of the prostatic fibers encircling the vesical neck. A projecting middle lobe can be to a greater or less degree eliminated by the écraseur, while the constriction of an hypertrophied neck can in like manner be cut through in one or more places, the vesical neck being sufficiently liberated to allow of its resuming its function.

Although a surgeon, by means of the rectal feel, of exploration of the prostatic urethra, and of the cystoscope, can generally decide whether a given case is suited, as far as regards the prostate, to the Bottini operation, yet he can never be certain. On numerous occasions in the performance of prostatectomy on individuals where previous to operation conditions seemed suited to the Bottini operation, the actual state of affairs found to exist have made it evident to me that the Bottini operation, had it been chosen, would have been either a failure or at least unsatisfactory. This in itself is a good reason why one skilled in the performance of prostatectomy is apt to find few occasions wherein the Bottini operation appears to be the one of choice. If an individual is quite elderly, say around 75 or over, and is suffering from the obstruction due to a middle lobe of not great size, it might be, in the absence of contra-indicating complications, that the Bottini operation would then be the one of choice.

In prostatectomy the results obtained are permanent. As regards the Bottini operation there are grave doubts on that point. Weir, in a recent discussion at the New York Academy of Medicine, recalled the fact that twenty-five years ago or thereabouts he and several other New York surgeons made a thorough trial of the original Bottini method and found it unsatisfactory, one of the chief reasons being that in the few cases where improvement followed the operation the betterment was only temporary. The advocates of the Bottini operation generally repeat the operation one or more times in cases where the improvement following the first operation does not appear lasting. It seems to me if a satisfactory result does not follow a primary operation of this description, that a repetition of it should not be employed, but that prostatectomy should then be substituted. To my mind the reason that the results following the Bottini operation may not show lasting qualities is in large measure due to the cicatricial contraction which gradually results from the healing of the burnt area. If the eschar be made through the bladder wall and into a projecting middle lobe lying posteriorly to the vesical neck, then it seems to me that a good result following the operation ought to show a fair and perhaps a satisfactory degree of permanency. If, on the other hand, the one or more eschars be made through the vesical and prostatic fibers at the vesical neck itself, then it seems to me that the immediate good result following the freeing of the contraction must be temporary, the resulting cicatrix leaving the part more contracted and rigid than before operation. In such an instance the fewer number of eschars and the less true destruction of the tissues making up the vesical and urethral wall, the better. In the performance of prostatectomy as I advocate it the vesical and urethral structures are left undestroyed, the prostatic obstruction alone being removed, consequently there can be no resulting contraction. Where prostatectomy has to be performed secondary to the Bottini operation the cicatrix which has resulted from the first operation may increase the difficulty of the second.

The surgeon who does only the Bottini operation, not having perfected himself in the performance of prostatectomy, is usually a dangerous adviser, since he is not equal to the emergency when a case offers itself which is not suited to his operation. Of course, in such a contingency the surgeon doing only the Bottini operation can refer the case to a surgeon who has perfected himself in the performance of prostatectomy; but what is perhaps more probable, the Bottini operation is tried, a failure resulting, or else any attempt at operation is discouraged, the case being allowed to die by default.

The cry of mortality is loudly raised against prostatectomy. It has seemed to me that that cry has originated largely from one of the three following sources: From those who know nothing about the operation; from those who do only the Bottini operation, and from those who have tried the operation and failed. I think I am fair in stating from my own experience in case an individual is otherwise sound in body, is not over 65 years or thereabouts of age, and has not marked urinary infection that the mortality from prostatectomy is not greater than 5 to 8 per cent. From that low level the mortality rises, dependent on the combination of adverse conditions which may be present. One should never hesitate to operate on the most desperate surgical risks through fear of injuring his statistics, for in the bad cases death accompanied by great suffering surely occurs if nothing is done, while if prostatectomy associated with thorough vesical drainage, is performed, death, if not averted, is peaceful, the patient thanking the surgeon for the comfort he has afforded, or—and this happens in a large majority of the worst cases—the patient completely recovers.

I admit that prostatectomy is not an easy operation. As the subjects are old and do not tolerate long continued anesthesia with safety, the operator should work with great rapidity. As a rule I have so far completed my operation that the anesthetic can be discontinued at the end of ten to fifteen minutes, the operation having been commenced the moment the patient becomes fully unconscious, and the last suture tied as consciousness returns. The wound should be so treated and the drainage tubes so adjusted that the patient remains comfortable after operation and free from painful surgical ordeals. Besides surgical, many medical and nursing details should be attended to with great strictness. The technique of the operation as I perform it, together with all the associated details, are fully described in my book of last year, "Diseases of the Genito-Urinary System," and consequently do not require reiteration in this connection. There is no reason why anyone naturally apt as a surgeon, who familiarizes himself with the theory of the subject and then practices it, should not master the operation and attain good results. If a surgeon keeps his patient under an anesthetic for two hours or so in the performance of the operation, and does not attend to all the details which experience has shown to be necessary, most, and perhaps all, of his patients may die. With such an experience blame and condemnation is apt to be unjustly attributed to the operation.

PERINEAL PROSTATECTOMY.*

PARKER SYMS, M.D.

Clinical Professor of Surgery in the New York University and Bellevue Hospital Medical College; Attending Surgeon to Lebanon Hospital; Member of the New York Surgical Society; Fellow of the New York Academy of Medicine; Member of the Society of Alumni, Bellevue Hospital; Member of New York State Medical Association, and American Medical Association.

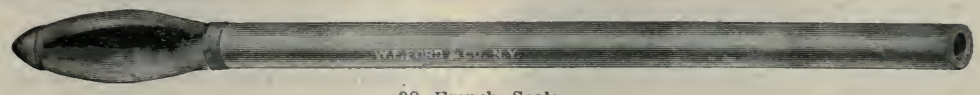
NEW YORK CITY.

Obstructive hypertrophy of the prostate gland causes so much misery and is productive of death in so large a proportion of aged men, that the profession must welcome every advance that is made in our means of treating this serious disease.

It is only in recent years that anything more than palliative treatment was applied to this condition, but in the last few years a great many new procedures have been devised, aiming at a more or less radical cure. The most prominent of these are prostatotomy by means of an electro-cautery knife which is known as the Bottini operation, and the various forms of prostatectomy. The author has devoted a good deal of effort and thought to the subject of prostatectomy and has devised a modification of one of the principal methods in vogue whereby he believes the operation has been very much simplified, and he also believes the mortality from operation by his method will be found to be much less than that attributed to other similar procedures.

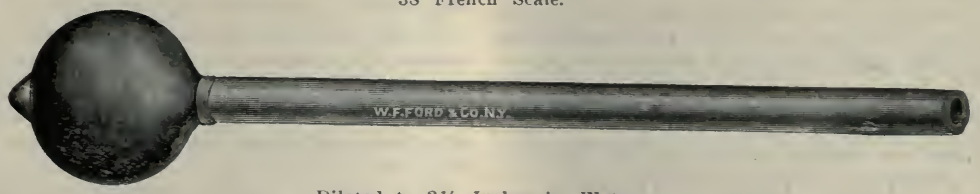
When the prostate gland has become so enlarged as to produce obstruction to the outflow of urine from the bladder, most serious results ensue. The obstruction may be but partial, preventing the patient from completely emptying the bladder; the retained or residual urine in time becomes infected, setting up a cystitis, and from then on the life of the patient is one of torture. In some cases the obstruction is so complete that the patient is unable to pass any urine until the bladder has become fully distended, then the overflow may pass off by constant dribbling. This condition is often mistaken for one of incontinence of urine. The inflammation often extends from the bladder up the ureters to the pelvis of the kidney, resulting in pyelitis. After months or years of suffering these patients finally succumb to exhaustion and find a welcome release in death.

Of course, much may be done for relief of these patients by the judicious and careful use of the catheter and by proper washing of the bladder, but the catheter life is at best one of discomfort and jeopardy, some patients finding no relief whatever thereby, and all of them in constant danger of acute cystitis and all its attendant disasters.



The Bottini operation was introduced about twenty-five years ago. It was at that time very extensively exploited and tested, but was found to be unsatisfactory and was finally abandoned. During the last few years it has been revived and it has to-day many enthusiastic supporters. Its object is to cut a groove through the middle lobe of the prostate so as to lower the urethral canal at that point; it is performed by introducing into the bladder an instrument like a curved urethratome. This instrument has a concealed cautery blade which is exposed when the instrument is in proper position, the electric current is turned on, burning its way through the floor of the urethra and into the surface of the lobe of the prostate. The author has had no personal experience with the Bottini operation and for many reasons it does not appeal to him as a sound surgical procedure. In the first place, it does not remove the hypertrophied prostate and can only partially relieve the obstruction in most cases. In the second place, it leaves a slough to separate and come away through the urethra. There being no other means of drainage than through the urethral canal, and this burned wound being in the presence of infected urine, it seems to the author that it can not be as safe a method as some of its advocates think it is. The only statistics which the author has read show that this operation is not free from danger, and that it does not result in complete cure in the majority of instances. The author believes that prostatectomy will be the favorite operation if the risks can be reduced so as to make it a feasibly safe procedure.

Unfortunately, prostatectomy, by most methods, has shown a large death-rate, though the results when the patient survived have been generally excellent. The author has so far been very fortunate, having lost no patient, and having had a complete cure in all his cases except the second one. In that case he was unable to remove the whole prostate on account of the fact that there had been a suprapubic cystotomy performed a year or two before he saw the patient, and at the time of his attempted prostatectomy there was a suprapubic abscess which had firmly fixed the prostate so that it could not be reached through the perineum. Since entering this field of work the author has been of the opinion that the high mortality rate was in part owing to the fact that the operations were too extensive and too complicated, and his object has been to devise some means whereby the prostate could be removed simply through a median perineal incision. He has felt that suprapubic cystotomy for this class of cases was a dangerous proceeding to be avoided. In an article entitled "Prostatectomy," read before the New York Surgical Society on Nov. 9, 1898, the author sug-



* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker and A. J. Ochsner.

gested the following modification of Alexander's method of prostatectomy: To make a small incision through the abdominal wall just above the bladder fold through which the operator could pass two fingers and with them push the prostate, bladder and all, toward the perineum, enabling him with a finger of the other hand to reach and enucleate the prostate through a median perineal incision. It will be remembered that Alexander accomplished this same object by making a suprapubic incision in the bladder, through which he passed two fingers of one hand and pushed the prostate down.

The author has never tried the laparotomy as suggested above, because he was able to devise a much simpler means for accomplishing this same object. At the meeting of the American Medical Association, held at Atlantic City, June 5 to 8, 1900, the author presented a bladder retractor which he had invented, which enables one to pull the bladder and prostate down into the perineum so that the lobes can be reached and enucleated with the index finger. This retractor consists of a soft rubber bulb, cemented on to the end of a strong rubber tube of a caliber of 38, French scale. It is introduced into the bladder through an opening in the membranous portion of the urethra, the bulb is then distended till it has a diameter of two and a half to three inches. This distension of the bulb is effected by forcing a definite quantity of water through the tube with a piston syringe. The tube is then clamped, and when pulled upon it will draw down the bladder.

38 French Scale.

Dilated to 2½ Inches by Water.

Parker Syms' Bladder Retractor, for Perineal Prostatectomy.

The author operates in the following manner: The patient is prepared by a few days' rest in bed, during which time he is kept on a milk diet, and his bladder is carefully catheterized and irrigated if he has cystitis. Ether narcosis is used; the patient is placed in the lithotomy position; the perineum and adjacent parts are properly shaved and scrubbed, and the urethra and bladder are again carefully irrigated with boracic acid solution. A free median incision is made which shall open the perineum from just behind the bulbous portion of the urethra to the vicinity of the anus. The dissection is carefully carried down to the urethra in the median line, and if possible to reach the prostate at once, it is freed as far as may be by blunt dissection, carried on mostly with the index finger of the right hand. From time to time the operator must introduce a finger protected with a rubber cot, into the rectum, so as to be sure that this organ is not wounded. A staff is introduced into the urethra and an incision about an inch long is made in its membranous portion. The staff is removed and a catheter passed through the opening in the membranous urethra and the bladder is again repeatedly washed. The author's retractor collapsed is introduced into the bladder through this opening in the urethra; when it is known to be well inside of the bladder it is dilated in the manner described above, with a quantity of water which is known to give it a diameter of fully two and a half inches. The rubber tube is clamped so that the water will not escape, traction is made on the tube till the prostate comes satisfactorily within reach, then an assistant holds the rubber retractor firmly, bending it up over the perineum and it will not be in the way. Now, with the index finger of the right hand, the operator perforates the capsule of the left lobe of the prostate and begins its enucleation. If the proper line of cleavage is found the lobe will shell out quite readily, and finally it can be grasped with vulsellum forceps and removed. Next, the operator removes the middle lobe in the same manner, and finally, the right lobe, thus completing the operation. Now the retractor is emptied by removing the clamp; it is withdrawn from the bladder and a large perineal drainage tube is introduced through the urethra to drain the bladder. The wound around this tube is thoroughly packed with iodoform gauze, the tube is secured by one suture, a pad is applied with a T-bandage and the patient is ready for bed. When in bed, the patient's bladder must be again irrigated through the drainage tube, and then continuous drainage is carried on by syphonage, a long tube being attached to the drain, the distal end of it being kept submerged in a disinfectant solution. The quantity of this solution must be measured so that one may know the quantity of urine being voided.

The gauze packing is removed on the fourth day and replaced by a much smaller piece. The drainage tube is removed on the fifth or sixth day, and thereafter the bladder is washed by means of a catheter passed through the perineum, until the wound has nearly healed.

These patients are allowed to sit up by the seventh to the tenth day. When the wound is considerably contracted a full-sized steel sound is passed through the entire urethra, at first every third day, then at longer intervals until healing is complete.

To one accustomed to operations on the prostate this particular method will be found to be comparatively simple and not a very difficult one to perform. Of course, one should be thoroughly familiar with work in this region and on these organs in order to use the best judgment as to how much should be done, and in order to be expeditious. When properly performed the operation is not a formidable one, the hemorrhage is very slight and the patients suffer comparatively little shock.

The author feels that prostatectomy will be proven in the future to be a thoroughly sound and proper procedure. He believes the death rate will be no more than is compatible with a condition that is in itself so grave and menacing. He feels, however, that prostatectomy should not be left as a last resort. It should be performed before the patient is in a dying condition, or not at all. Any man who is not physiologically very old, whose arteries are in fair condition and who is not suffering from marked kidney lesion may be expected to undergo this operation with comparative safety, pro-

vided it has not been left till his bladder is badly inflamed and till he is suffering from sepsis. The author feels assured that by his method every hypertrophied prostate may be removed through a simple median incision in the perineum, and after this is accomplished it will be seen that there is not a formidable wound; in his experience it has been found that the patients have been actually better the day after the operation than they were the day before, on account of the relief afforded by the immediate drainage of the bladder.

The author has operated on nine of these patients; the last six were done in the manner just described. His first case was done by the method of Alexander. His second case was incomplete for reasons already stated. His third case was done entirely through the perineum, the prostate being easily reached, an assistant making pressure on the abdominal wall, which was thin and yielding. This was before he had devised his retractor.

His patients have ranged in age between 53 and 75 years. All have had cystitis except one case. Two of his patients had bladder stones—one had a simple large calculus, the other had five of moderate size. The residual urine in his cases varied in amount from 3 to 5 ounces.

The author's patients have all lived. In his second case relief was only partial. In all the other cases cure has been complete, the patients having no obstruction to the passage of urine and no remaining cystitis and no residual urine. In two of his cases there was incontinence of urine for some weeks, but this condition gradually subsided and the patients regained control of the bladder.

50 W. Forty-seventh Street.

NOTE:—Since presenting this paper the author has learned that one of his patients has had some trouble from incontinence of urine. Otherwise no unfavorable result has been reported.

PROSTATECTOMY VERSUS PROSTATOTOMY IN THE RADICAL TREATMENT OF SENILE HYPERTROPHY OF THE PROSTATE.*

RAMON GUITERAS, M.D.
NEW YORK CITY.

In senile hypertrophy of the prostate there is sometimes obstruction to the outflow of urine, due to an enlargement or deformity of the middle or lateral lobes, giving rise to a series of disagreeable symptoms, such as frequency of urination, pain, tenesmus, burning or acute retention, and resulting in complete or incomplete retention, followed in nearly every case by cystitis, pyelitis, and fatal nephritis or pyelonephritis.

With the object of overcoming this condition the following various procedures have been resorted to: The use of the catheter to relieve the retention by drawing off the urine as frequently as indicated by the amount of residuum; suprapubic fistula, by means of which an artificial urethra is made in the hypogastric region, through which the patient urinates, or draws his urine by a catheter or tube; dilatation of the prostatic urethra with sounds or dilators every few days; galvano-puncture, by means of a platinum needle attached to the negative pole of a galvanic battery, and inserted into the gland; hypodermic injections of iodid of potassium and iodin, or ergot and alcohol into the gland; ligation of the internal iliac arteries; castration; vasectomy; prostatotomy, and prostatectomy.

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker and A. J. Ochsner.

Of these various methods none are now employed in this country excepting catheter life, prostatectomy and prostatotomy. The catheter can at present be said to be used only when the patient is in need of an operative procedure for the relief of his urinary symptoms, and when it is considered dangerous to do a prostatectomy or prostatotomy on account of his general condition; it is also used prior to either of the operations, with the object of treating the bladder and reducing prostatic edema or congestion. The catheter is also employed in the after-treatment following prostatotomy and prostatectomy until an accompanying cystitis has been cured and the bladder has regained some of its tone. In many cases drainage by a retained catheter may be necessary. A description of catheter life and the uses of the catheter in prostatic hypertrophy has been given by the writer in a previous article.[1]

PROSTATOTOMY.

This consists in making incisions through the gland by the knife or cautery, with the object of reducing the impediment. During the latter part of the nineteenth century great interest was taken in this procedure, which was considered the coming operation for the relief of senile hypertrophy, and the leading genito-urinary surgeons of the world advocated the operation.

Robinson recommended incising the prostate through the rectum. His method consisted in introducing his left forefinger into the gut as a guide, and then inserting the knife along it and dividing the prostate into two halves.

Harrison, at the International Medical Congress in Copenhagen, in 1887, advocated performing an external perineal urethrotomy, and then inserting the knife into the prostatic urethra, and dividing the prostatic bar on the floor of the gland, after which he stretched the prostatic urethra forcibly with his fingers or a sound. He was personally very much pleased with this method, and many surgeons, both in this country and abroad, followed his footsteps.

Mercier devised the prostatotome for cutting the middle lobe of the gland through the urethra. This resembled the Bottini incisor in that it had a sharp male blade which he drew forcibly through the floor of the prostatic urethra, making an incision through the impediment.

Gouley modified Mercier's operation, inserting the instrument through a perineal incision into the urethra and cutting or punching out segments of the enlarged gland. In this way he often removed large portions of the prostate.

Maisonneuve then devised the sécateur, by means of which he incised the prostate through the floor of the urethra. It was one of the most ingenious instruments ever brought before the public, although not so useful or as lasting as his famous urethrotome. The instrument was shaped like a sound. In the center of the convexity, working on a pivot and lying concealed in the groove, as far back as the end of the instrument, was fastened a cutting blade. After the beak was caught behind the vesical base of the gland the blade was made to move in the arc of a circle, thus making an incision in the gland through the floor of the urethra and landing in a slot in the straight part of the shaft, where it again concealed itself, or else was pushed forward to its former position before the instrument was withdrawn.

In 1877, Bottini of Padua, Italy, invented the galvano-caustic incisor, an instrument very similar to Mercier's in its general form, but differing from it in that

1. N. Y. Med. Jour., March 2, 1901.

the blade was connected with a storage battery, and cauterized instead of simply cutting. He performed many operations with this instrument, and published statistics which seemed too good to be true. Other surgeons in France and England who took up this procedure, did not have such favorable results, and looked upon it as a failure and one of little merit. Some three years ago, however, Freudenberg of Berlin, modified the Bottini instrument in such a way that it is now the most valuable that has yet been devised for the operation of prostatotomy. He used a broader blade made of irido-platinum and utilized the hollow shaft of the instrument on either side of the slot, to allow water to flow through and keep the instrument cool during the operation. The Freudenberg instrument was superior to any of the cutting ones in that it gave rise to less hemorrhage, and there was less danger of infection, for the cauterizing knife

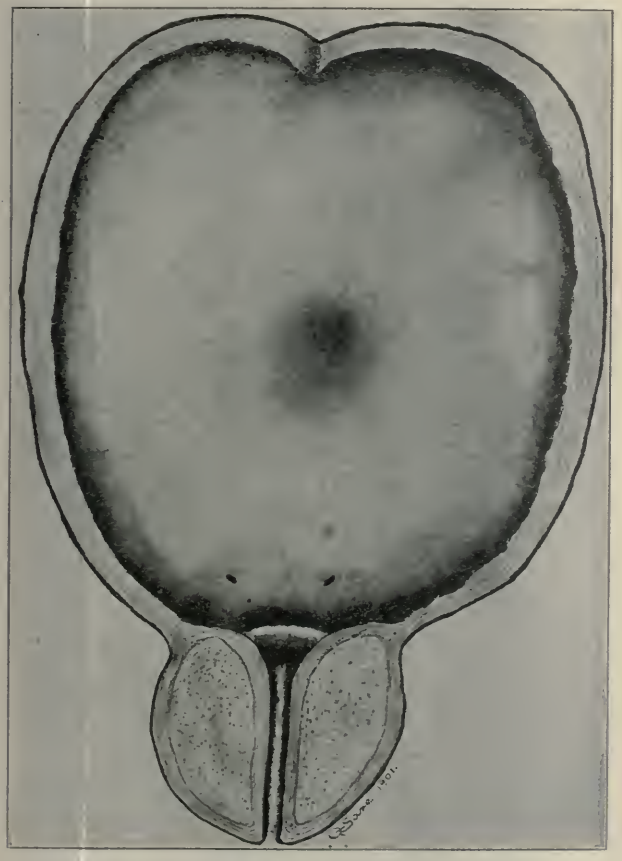


Fig. 1.—Prostatic bar. Bottini's operation.

as it went through the gland sealed up the vessels, preventing bleeding and also closing them against infection. Besides this, the tissues which were burned for some distance on either side of the incision were thrown off as a slough during the three or four weeks following the operation, thus producing a gutter of considerable width. It can therefore be seen that this operation diminished the prostatic impediment, not only by making one or more gutters through it, but by shutting off the blood supply and thus causing atrophy of the gland. Prostatotomy by the Freudenberg-Bottini method is then the sole surviving operation used at the present day, and is one which we must consider under the so-called radical operations for the relief of prostatic hypertrophy. It is employed with a few modifications in the same manner by all surgeons who employ it.

The results of prostatotomy are most favorable, and I will quote from Freudenberg's last article[2] in which he collected 753 cases. Of these there were 622 successes, 44 deaths—12 of which were not positively due to the operation—but the total of deaths was 5.8 per cent., and 17 failures.

The Technique of the Bottini Operation.—The patient should lie on his back on the table. He can be operated on either under local anesthesia by cocain or eucain, or under general anesthesia by ether, chloroform or nitrous oxid gas. Personally I prefer general anesthesia by nitrous oxid gas. On the patient's left should be hung a fountain syringe, which contains water for cooling the instrument, and, on a stool near the patient's waist, the battery should be placed. A soft rubber catheter, lubricated with glycerin, is passed into the bladder, the urine is drawn off and the bladder is washed out with boracic

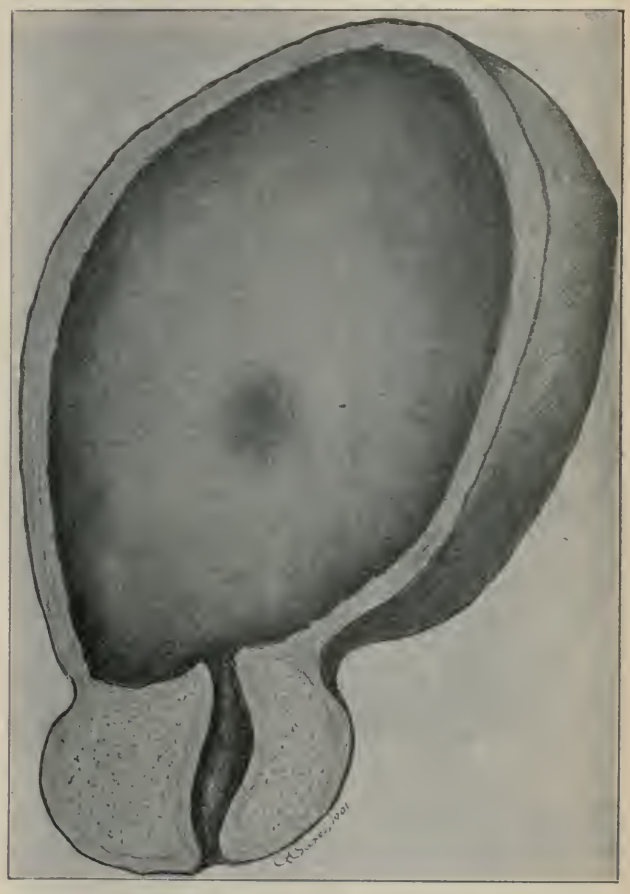

Fig. 2.—Prostatic bar. Side view.

acid solution and 6 ounces of the fluid allowed to remain in, after which the incisor is introduced and the operation performed. If a local anesthetic is to be used the bladder should be emptied, after which, before the catheter is withdrawn, a urethral hand syringe with a 4 per cent. solution of eucain or cocain is injected into the bladder and the posterior and anterior urethra as the catheter is being removed. From this moment the work should be done quickly and accurately, and I have observed that the more quickly the operation is performed after the injection of the anesthetic in cases of local anesthesia, the less painful it is to the patient.

If cystoscopy is performed the time required for it will usually be sufficient to allow the effect of the anesthetic to pass off before the actual operation is begun, and for this reason I think it advisable either to use the cysto-

2. Centralb. f. d. Krankh. d. Harn und Sex. Org., 1900.

scope at an earlier date, or to again inject a local anesthetic after the cystoscopy. It seems to me for this reason that it is advisable to omit the cystoscopy just before the operation, as advised by some, and to consider it as having been performed previously when the patient was examined. Therefore, after the cocain has been introduced into a clean, empty bladder and urethra, the catheter should be quickly pushed back again and six ounces of water injected into the viscus, after which, the catheter being quickly withdrawn, the incisor is introduced. If it catches in the deep urethra, the pelvis should be elevated; this will allow it to enter the bladder if the handle is depressed and a slight upward push is given to the instrument. If it still catches the patient must be anesthetized. In four cases under eucain anesthesia I have failed to pass the instrument. I afterwards operated in three of these under nitrous oxid gas

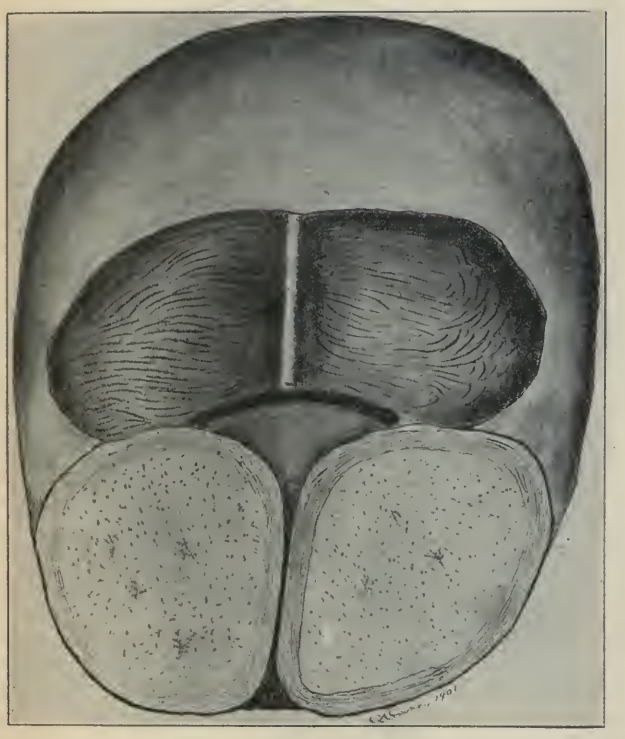

Fig. 3.—Enormous lobes; bar; enucleation by perineal method.

anesthesia and introduced the instrument without difficulty. The obstruction is generally a spasm of the vesical sphincter.

After the instrument is in the bladder its beak is turned downward and drawn forward until it catches against the base of the gland. The left forefinger is then introduced into the rectum to see if the instrument is in place. If so it should be held there, the connection made with the battery and a current of 45 amperes turned on, after which the wheel of the handle on the instrument should be turned, drawing the knife through the gland and burning a furrow in it. The current should then be shut off while the instrument is being rotated to one side at right angles, when it should again be opened and an incision made through one of the lateral lobes, then in a similar way through the other.

After prostatotomy a catheter should be retained for a few days, the patient should be given some urinary antiseptic and a milk diet, and should be instructed to drink large quantities of water. Ten grains of urotropin given three times a day is the best urinary antiseptic.

In cases in which the gland is irregularly enlarged and the posterior urethra distorted by the hypertrophy, it is sometimes advisable to perform a perineal urethrotomy for drainage after the operation. In a number of cases after the operation there was difficulty in introducing the catheter. This was caused by a straight cut having been made from the center, or most dependent part of the vesical base of the gland, down through it, which not only may not have gone into the urethra, but which may have pushed a portion of the gland to one side, thus obstructing the canal more than previous to operation. In these cases I should advocate an immediate perineal urethrotomy, with the introduction of a perineal drainage tube of large size, 34 to 36 French. In an operation under local anesthesia, by a colleague, the patient shrank back and allowed the beak of the instrument to slip forward over the convexity of the gland, thus cut-

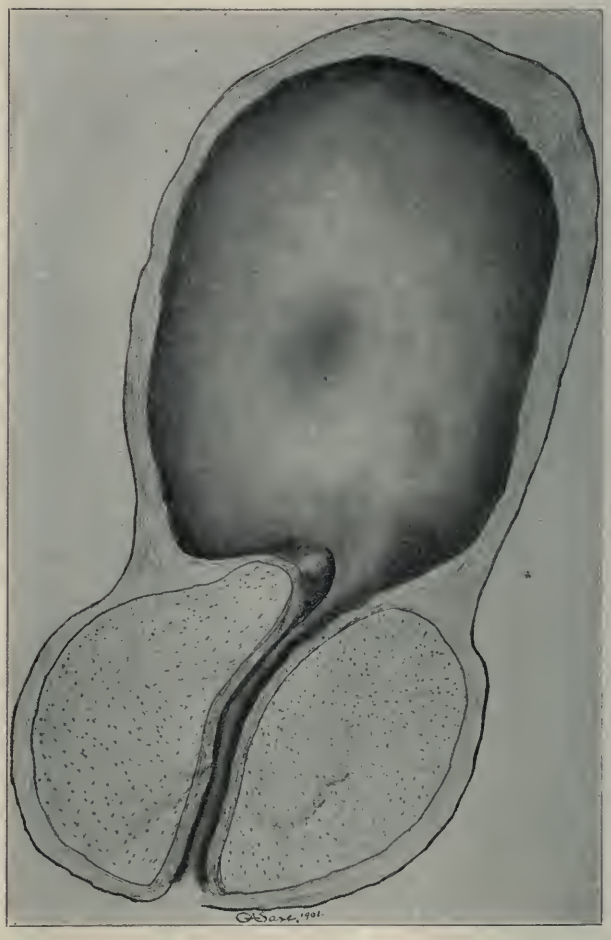

Fig. 4.—Side view. Enormous lobes; bar; perineal prostatectomy.

ting into the membranous urethra and perineum. A perineal urethrotomy was not performed at the time, necessitating a further operation for retention; death from uremia and sepsis followed. This patient would have been saved in all probability had a perineal operation been performed at the time. I have seen other cases in which I am sure that had I performed a perineal section, my patients would have had a better result.

PROSTATECTOMY.

This is the operation by which the gland is removed. For a number of years attempts have been made to remove pieces of it through perineal incisions into the urethra and suprapubic incisions into the bladder. Within the last ten years, however, much advance has

been made in this operation, until we now have operations by the suprapubic, perineal, and the combined methods, as also those by extensive dissections. This last class of operations, namely, those involving extensive dissections between the rectum and the prostate gland, as Zuckerkandl's, Von Dittel's, Rydygier's and others, are now never used.

McGill can be said to be the father of the advanced movement in prostatic surgery. He began by removing small pieces in an unscientific way through the bladder after a suprapubic cystotomy, and improved his technique with experience until he succeeded in performing a fairly satisfactory enucleation. His method was briefly as follows: He performed a suprapubic cystotomy and attached the bladder to the abdominal wall; he then inserted curved scissors through the bladder, cutting away as much as possible of the prostatic protrusion

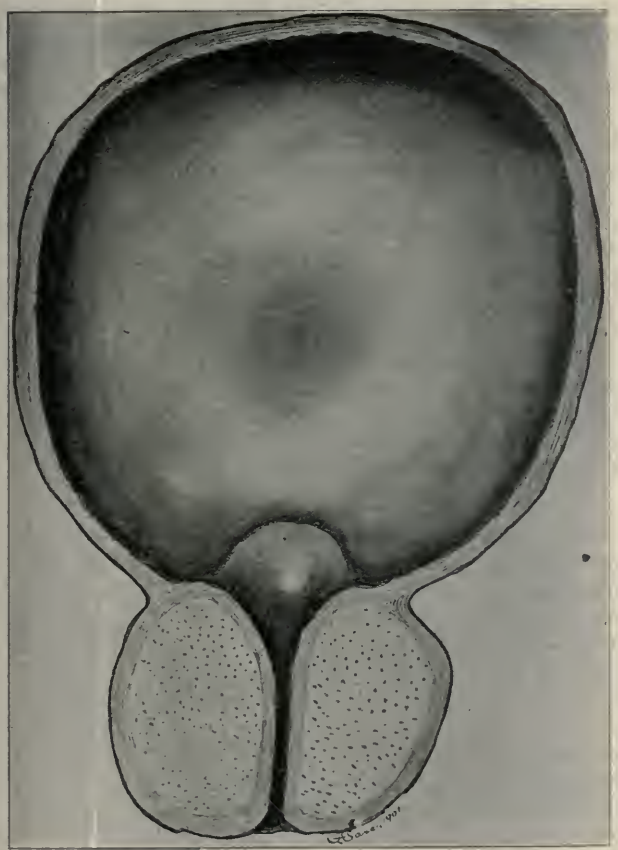

Fig. 5.—Middle lobe hypertrophied; enucleation, suprapubic method.

and helping the process by grasping the growth with the forceps and pulling it up while he cut beneath. In this way he cut through the tissues over the most prominent portion, enabling him to insert his finger and enucleate, aiding himself by means of the forceps. By this means he removed pieces varying in size from a bean to cricket ball, going to prove that in these latter cases he had evidently performed a complete enucleation. After the gland was removed the bladder was drained for a few days.

Bellfield modified McGill's operation by advocating the additional operation of perineal urethrotomy to facilitate drainage. Fuller has since then improved the technique, and advised counter-pressure by the fist against the perineum. This pressure certainly facilitates the removal of the gland. He also drains through the perineum after a boutonnière operation. Other surgeons think it better to enucleate through a perineal incision.

Nicoll was the first to outline a well-defined method of procedure by this route. He performed a suprapubic cystotomy and attached the bladder to the skin; he then made an incision in the perineum as one would for a perineal urethrotomy, and a second incision at right angles to it in front of the anus, forming a T. He then dissected up in the perineum anterior to the rectum as far as the prostate, and having cut through the capsule he inserted his forefinger of the right hand between it and the gland; then, introducing the fingers of the left hand into the bladder suprapubically, he made counter-pressure while he enucleated the gland with the finger of the right hand. Sometimes he used instruments to assist him. He drained through the urethra by means of a retained catheter without performing urethrotomy.

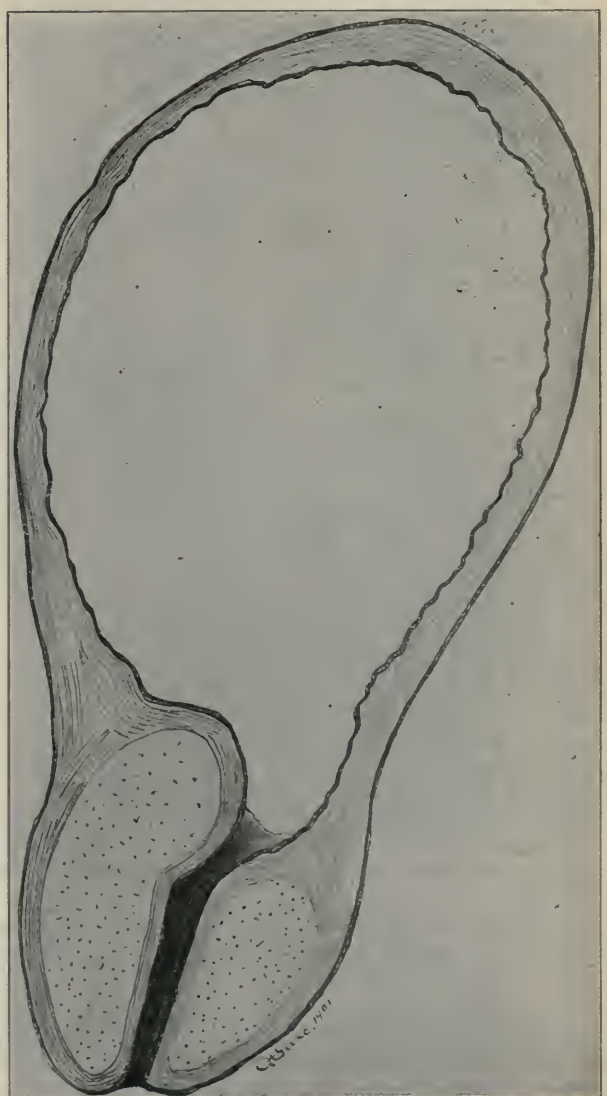

Fig. 6.—Hypertrophied middle lobe. Profile view. Semi-diagrammatic.

He packed the perineal wound with gauze, took out the stitches suprapubically, and allowed the bladder to fall back again.

Alexander modified Nicoll's operation by going into the prostate through a perineal incision made into the membranous urethra up to the apex of the gland. He then incised the capsule and inserted his finger in it for

enucleation, making counter-pressure through an opening in the bladder while he enucleated. He drained both suprapubically and through the perineum. In both these methods the bladder had to be opened suprapubically.

Syms of New York endeavored to obviate this necessity by an ingenious device, consisting of a hard rubber tube with a soft rubber balloon at the end. This he inserted into the bladder through a perineal opening, after which he inflated the bag with water, and had an assistant make gentle traction upon it, thus drawing down the base of the gland and steadying it while he enucleated through the perineal incision.

Methods.—Two methods of prostatectomy are employed by the author of this paper: 1, the vesico-rectal method, presented in a paper[3] read before the thirteenth International Medical Congress in Paris; and, 2, the

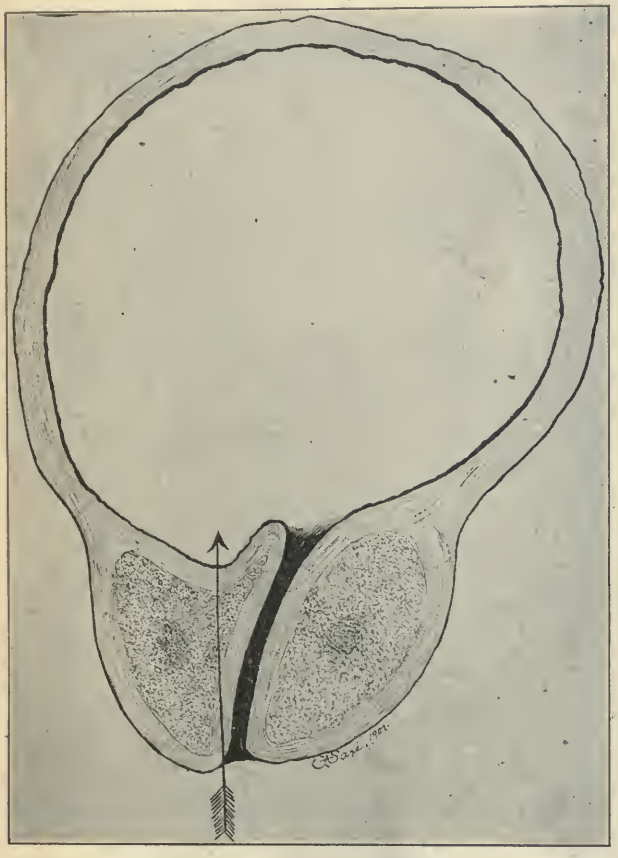

Fig. 7.—Tortuous prostatic urethra. Bottini useless. Semi-diagrammatic.

perineo-prevesical method, using counter-pressure in Retzius' space, presented before the third Pan-American Medical Congress in Havana.[4]

The vesico-rectal method is briefly as follows: After a suprapubic cystotomy, insert the two fingers of the left hand into the rectum, and the index finger of the right hand into the bladder and palpate bimanually; pass a pair of sharp pointed, curved scissors into the bladder and thrust the points through the most prominent part of the gland, or the portion just behind the internal meatus and open the blades, thus tearing the tissues covering the gland; then insert the finger tip into this tear and work it around between the gland and the capsule, making counter-pressure with the two fingers in the rectum. After the gland has been enucleated pass the scissors in again and cut through the floor of the prostatic urethra to prevent the formation of a pocket, then bring the patient into the lithotomy position and do an external perineal urethrotomy and insert a perineal tube for drainage. Insert another tube into the bladder suprapubically and sew the bladder wall tightly up to it. Close the abdominal wall above and below the tube. Leave the suprapubic tube in for one week, and the perineal tube for three or four weeks. This is the quickest method of removing a prostate with which I am familiar.

The perineo-prevesical method consists in first making an incision suprapubically into the prevesical space without going into the bladder; then placing the patient in the lithotomy position and doing an external perineal urethrotomy; next passing a pair of sharp-pointed scissors into the perineal opening, cut through the capsule of the prostate, after which the tip of the right index finger is pushed in between the capsule and the gland and enucleation begun, while counter-pressure is made over the base of the prostate by the finger in the prevesical space. After the gland has been removed a perineal drainage tube is inserted into the bladder, and the skin and superficial perineal fascia sewn up to it. The suprapubic wound can then be closed, or a drain can be left in for a day or so. I consider this the safest method of performing a prostatectomy that has as yet been devised, although not so rapid as by the vesico-rectal method.

After all prostatectomies the patient should have 1/30 of strychnia hypodermically and a pint of hot saline solution, to be retained. After this strychnin, hot saline enema, water by the mouth, hot bouillon, or whisky alternately every four hours, so that every hour he receives something. Water should be pushed from the first, and if he vomits, more should be given.

RESULTS.

In reading the literature of the last few years we find 152 well-reported cases of prostatectomy, in which the operation was performed by the suprapubic, the perineal, and the combined methods. Of these 95 were suprapubic, and the remainder were by the perineal and combined methods. There were 25 deaths and 127 recoveries. The recoveries were spoken of as failures in 17 and successes in 27; the remainder as improved, recovered, or good results. It is difficult, therefore, to say what the results are in these cases of recovery, excepting in the ones spoken of as failures, cured or successful, for a recovery means either that the patient did not die, but has recovered from the operation, or that he has recovered his former health.

COMPARISON.

In comparing the results we have obtained from the tables quoted of prostatotomy and prostatectomy we note that in the former, prostatotomy, in 753 cases there were 622 cures, 44 deaths and 87 failures. In the latter, prostatectomy, there were 152 cases, 110 recoveries, including cures, successes, recoveries, good results and improved; 25 deaths and 17 failures. Figuring by the percentage in prostatotomy there were 82.5 per cent. of cures, 5.8 per cent. of deaths, 11.5 per cent. of failures; while in prostatectomy there were 72.3 per cent. of cures or improved, 16.4 per cent. of deaths and 11.2 per cent. of failures. From this it will be seen that the mortality in prostatectomy is three times as great as it is in prostatotomy. In those who survive, the failures are about as frequent as in prostatotomy, but the recoveries are better. It is difficult to say

3. N. Y. Med. Jour., Dec. 8, 1900.
4. Phila. Med. Jour., April 20, 1901.

what a cure is in these cases. It seems to me that if a patient can empty his bladder of all the urine excepting perhaps .5 ounce of residual that the result obtained is first class, especially if he is relieved of his symptoms. Of course, the surgeon and the patient look upon the results in a different way. If the amount of residual urine is very much decreased, and the condition of the urine better, the surgeon considers it a good result; the patient, however, does not consider the result good unless the disagreeable symptoms are removed, such as the frequency of urination, pain, tenesmus and burning. It may be said that in those recovering, the results from prostatectomy are much better and more permanent than in prostatotomy. In prostatectomy we never have to perform the operation but once, whereas in prostatotomy we must often repeat it.

The indications that will decide us as to which operation should be performed are: 1, the age of the patient; 2, the size of the prostate, and, 3, the condition of his kidneys and bladder. It may be said in a general way that middle-aged men with very large prostates as felt through the rectum, having good kidneys and bladder, are cases for enucleation, while very old men with slightly damaged kidneys, and prostates that do not feel very large on rectal examination, yet causing considerable urethral impediment, are cases for prostatotomy.

Age is important, as the older the patient the lower his resisting power, and the more liable he is to death from shock and asthenia, therefore in a very old man, if the prostate is of the right variety, a Bottini operation would be performed, and cases of men over 90 have been reported as having been operated upon by this method successfully. Old age, however, is not an absolute contra-indication to prostatectomy, as men over 75 years of age, having good kidneys, non-infected urine and a very large prostate, may undergo prostatectomy.

Regarding the size and shape of the prostate, it may be said that very large prostates, as felt per rectum, are favorable for enucleation. Smaller ones, that is to say in which there is not much enlargement on rectal touch, but in which there is a distinct impediment in the prostatic urethra on introducing the instrument, together with considerable quantity of residual urine, are best for prostatotomy.

It is impossible to tell how large a prostate is, although one experienced in this class of examinations has a decided advantage over others, for when added to a feeling of enlargement of the gland in the rectum we have that of an impediment in the posterior urethra as imparted to the sound or searcher, and are able to judge of the increased length of the canal by hooking its beak behind the middle lobe, as well as noting the amount of residual urine present and the distance to which we have to introduce the instrument to obtain it, we have a fair idea of the gland.

In cases in which the gland seems very large by rectum, and in which there is a urethral impediment at seven inches or more, and the urethra is lengthened, we can say that hypertrophy of the lateral lobes probably exists, but if the gland is small by rectum and a similar condition exists, we must think of a middle lobe being principally involved.

Cystoscopy tells us something of the contour of the base of the gland, although it is of little value in some cases, on account of not being long enough to enter the bladder, and in others because the surgeon is not able to outline distinctly the irregular vesical base.

Regarding the condition of the kidneys and bladder, it may be said that the bladder is the least important, because it makes no difference how badly inflamed it may be, treatment will do much to benefit it by means of internal urinary antiseptics and irrigations through a catheter. An involved bladder does not count so much against the operations as kidney involvement does. It is surprising to see how often a bladder can empty itself almost entirely after a prostatic operation even if it has been considered atonic before that time, and sometimes when years of catheter life have been passed. Diseased kidneys, however, whether medically or surgically involved, are always contra-indications to surgical interference on the prostate, as in such cases a post-operative renal congestion followed by uremia and death may take place. If then the kidneys are diseased and an operation demanded, a prostatotomy should be the one of choice, as statistics show that the danger is very much less.

I will endeavor to point out the operation which the surgeon should choose in performing a prostatectomy or prostatotomy by means of some illustrations of prostatic specimens. Figure 1.—We have a prostatic bar, acting as a dam against urinating. The gland is not much enlarged. It is a typical case for a Bottini operation, prostatotomy. Figure 2.—This is also a prostatic bar, but the lateral lobes are so enlarged that an enucleation by the perineal route should be performed, as it will be easy to reach them from below, and little could be accomplished by prostatotomy. In Figure 5, the lateral lobes are not much enlarged, but the middle lobe is very much so, and prostatectomy by the suprapubic method through the bladder would be much easier, as it can not be so well reached from below as from above. Figure 7.—Here the gland is not much enlarged, excepting in the left lobe, but the urethral floor of the prostatic urethra is elevated. We would encounter considerable difficulty in performing a prostatotomy, for after the incisor has been inserted in the bladder, the beak turned downward and the instrument drawn down in the median line as far as possible, it will be seen that it would not be over the prostatic urethra, but to one side of it, and the furrow burnt through the gland would leave an island in the center which might be pushed to one side, thus impinging upon the urethra. On the other hand, if the incision were not sufficiently long to meet the urethra below, it would simply result in a blind sac leading off from the bladder into the gland, as a result of which he would not have so good a urethra as before the operation. In such cases it will be necessary to perform a perineal section after a prostatotomy; to explore the prostatic urethra and the bladder neck thoroughly with the finger; stretch the parts, if necessary, and insert a large perineal drainage tube.

75 West 55th Street.

[The remainder of this Symposium, with discussion, will appear next week.]

The Cleansing of Floors.—Dr. Owen recommends a finish on hospital floors of wax, linseed oil, turpentine, floor finish and benzine in the following proportion: Wax, 5 pounds; linseed oil and turpentine, 2 gallons each; floor finish (permanere), 1 gallon, and benzine, 10 gallons. This is applied once a week and laid on with a piece of cotton, brushed and polished with a cotton mop. He believes that too much floor scrubbing is responsible for some of the sickening odors which are due to decomposition taking place both in and on the floors. The danger of fire from the use of this material is very slight if only a small quantity is kept on hand to use at a time.—*Phila. Med. Jour.*

AUTOPLASTIC SUTURE IN HERNIA, AND OTHER DIASTASES.—PRELIMINARY REPORT.*

L. L. McARTHUR, M.D.
CHICAGO.

Without entering into a discussion of the relative merits of suture materials possible or desirable, all of which can be found in our text-books, it shall be the aim of this brief and preliminary communication to show the feasibility as well as the desirability in certain situations of utilizing the patient's own living tissues as the resisting medium to future hernia. While at work with an inguinal hernial operation the idea occurred to me that it would be feasible to utilize a strip of the tendinous portion of the external oblique, which, possessing fibers in the adult from 5 to 6½ inches in length, would have sufficient strength to act as a substitute for the absorbable kangaroo sutures. Experiments on dogs and operations on the human being have proven to me the feasibility of the procedure; it remains for the future to determine the actual value of the suggestion.

Mentioning in passing the more pertinent of the autoplastic hernial procedures that have been recommended by various surgeons, in order that they shall not be confused with the present suggestion. This in nowise is intended (as are all the other methods) as an obturator to the inguinal canal. I would recall McEwen's treatment of the sac, as a pad at the internal ring, or Wölfler's autoplasty with the lower segment of the rectus muscle loosened from its sheath and drawn out to the position of the canal, or Poullet's dissection out of the tendinous insertion of the adductor magnus and grafting it upward into the canal, or Graham's similar treatment of the upper end of the Sartorius. Autopsies held long afterwards have demonstrated the complete absorption of the McEwen treated sac; while atrophy of the muscular structures utilized as obturators to the canal has been observed. The only suggestion similar to mine with which I am familiar is that which was made by Vulliet in cases of nephropexy, he being driven to this expedient when all other methods of suture, absorbable or non-absorbable, had given occasional failures. You will recall that in that position he recommended the dissecting out of a portion of the tendon of the longissimus dorsi, leaving its lower end attached. With this he perforated the capsule of the kidney, bringing the free end then into the wound for fixation. With such a living suture it was possible for him to have a permanent suspensory ligament. His recommendation has not met with the recognition it perhaps deserved, because, 1, in that situation it required an extra three and one-half inch incision above the usual wound, exposing the tendon at the transverse process of the first lumbar vertebra. 2. Simpler, equally successful, procedures came into use. In the case of inguinal hernia, however, the tissues lie immediately at hand; the skin incision need be lengthened but an inch to one and one-half inches, when the living tendons with their fixed bony insertion below can be separated in any desired size. It thus becomes an easy matter to utilize them for the suture of any hernial procedure; requiring, however, a running instead of an interrupted stitch.

Technique.—Any of the accepted operations, the Bassini, or the Andrews-Girard, operation can utilize this material without great variation in the technique. The skin and fat having been cut, exposing the external ring, the latter is prolonged upwards, the line of separation paralleling exactly the tendinous fibers of the external oblique muscle to its commencing muscular insertion. This divides the aponeurosis of the external oblique into an external and an internal flap, the cut edges of which can easily be raised from their contact with the internal oblique. The sac having been treated as the operator may

Fig. 1.—Schematic representation of two strips of tendon of external oblique, ready for suture; canal represented as opened; sac ligated and dropped back.

prefer (Duplay-Cazin) a bundle of those white fibers which enter into the formation of the internal pillar of the ring are then split off from the edge of the internal flap of the external oblique quite up to their insertion in the muscle belly, where they are cut loose from the muscle but left attached to the spine of the pubis. This strip should vary in width from one-eighth to four-sixteenths inch, according to the development

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker, and A. J. Ochsner.

of the tendinous fibers, which in children and women are not so strong as in the male adult. In case a Bassini is done, a similar strip is taken from the outer flap, the lower end of which strip terminates in the fibers of the external pillar of the ring. At this stage the opening presents the appearance of a shoe ready to be laced up. The operation is then completed according to the choice of the operator, a Bassini or an Andrews imbrication or a Girard, using these strips as

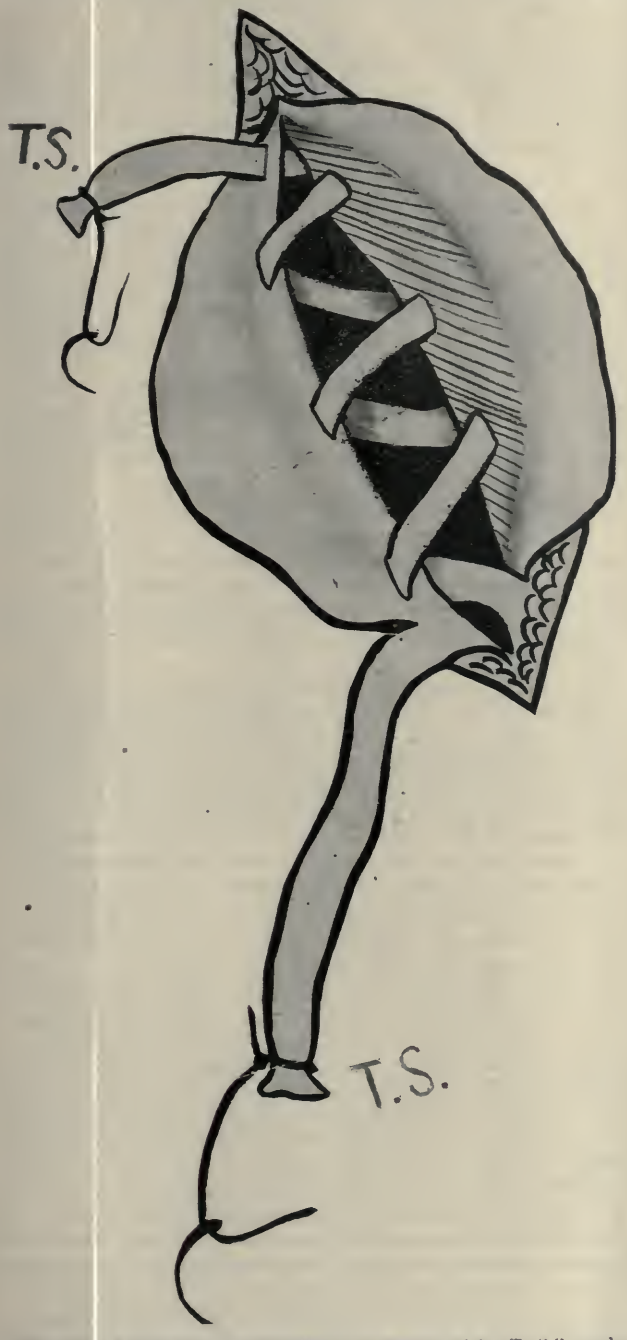

Fig. 2a.—Schematic representation of suture with "T. S." tendon strip for deep layer; inner flap to inner aspect Poupart's ligament. Artist has included inner flap of external oblique tendon as in Andrews'.

suture material for a running stitch. As an easy means of handling, and for the purpose of avoiding infecting the graft suture, a strand of No. 3 silk is tied (with a single knot) tightly to the free end, this silk threaded in the ordinary needle, and the tendon graft drawn through the tissues to be united, one for the deep row of stitches, the other for the superficial layer. The first stitch is so applied as to give the desired lumen to the new external abdominal ring, using the one terminating in the internal pillar for the first suture, the remaining one for the superficial layer of buried stitches. The end of the suture strip can be fixed by making a simple knot in it; but one or two stitches through and back as the tailor fixes his thread, will also serve the purpose. The treatment of the cord can be by either method that suits the operator's fancy—Bassini or An-

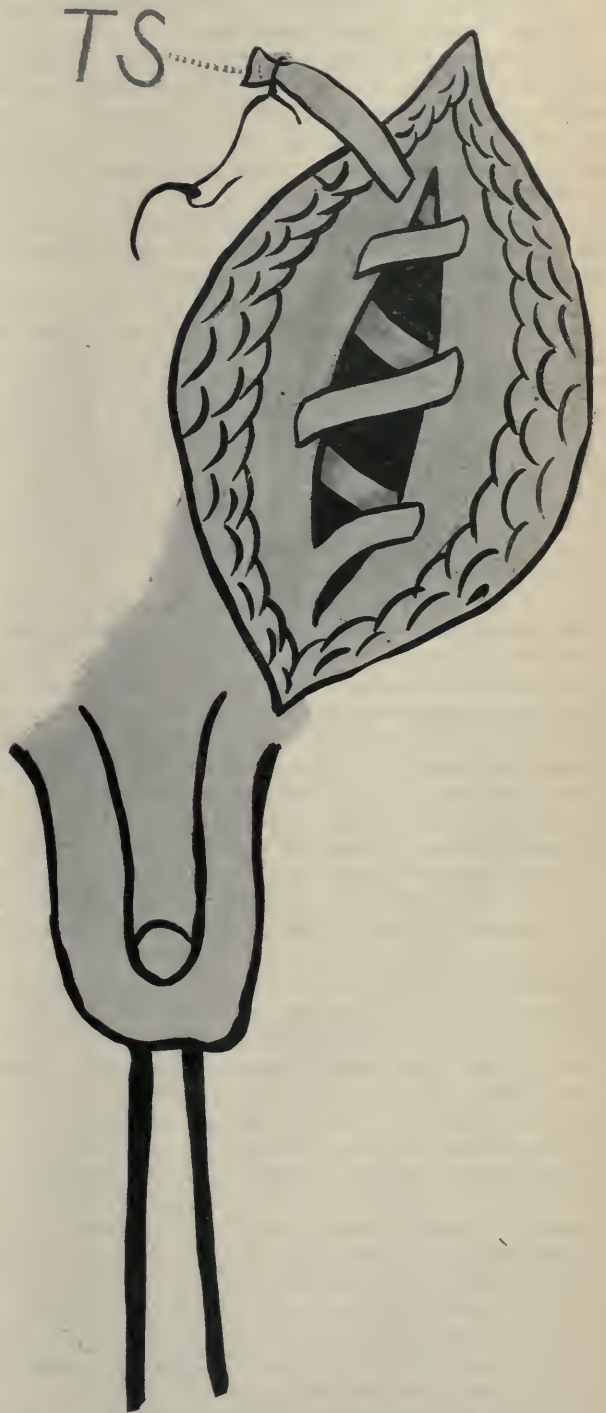

Fig. 2b.—Similar representation of suture with "T. S." outer flap to anterior surface of inner flap, when using Andrews' Edge-to-edge with Bassini.

drews. The skin and fatty layer can likewise be closed with the suture most in vogue with the person operating. The writer's practice usually has been with interrupted silkwormgut stitches, no drainage, and sealing with

iodoform collodion. While I have had a large number of hernial operations in the past, since commencing this method of suture I have had twelve[1] cases in which to try it, in all of which a perfect primary union was obtained, with an unusually satisfactory convalescence, the temperature not rising as it usually does during the absorption of the animal sutures, with in these few cases less than usual of the indurated boggy area surrounding the wound. Some of my colleagues have likewise tried the operation, making in all seventeen cases of which I have personal knowledge.

Realizing, as I do, how nearly perfect our absorbable suture material has now become, I should not have the temerity to present this paper did I not believe it to possess undoubted additional merits, viz.: 1, the obtaining of a living suture; 2, lessened chance of failure through avoidance of introduction of dead or foreign tissue; 3, the incorporation in the resisting cicatrix of organized white fibrous tissue; 4, the applicability of the same procedure to other situations.

By similar experiments with aponeurosis of external oblique of the dog, I am able to demonstrate that the tissue heals *in situ*, is not absorbed, does not slough, and I present microscopic specimens thereof in verification. Animal ligatures dissolving in one to two weeks no longer exert a retaining influence, while these grafts living, as white fibrous tissue largely does by imbibition, remain permanent. Indeed, the well-known heteroplastic tendon grafting for loss of portions of tendinous structures should teach that this graft should likewise.

It will at this date be generally accepted as true, I think, that failure of cure in hernial operations by any of the recognized methods is practically always due to associated infection, for the Bassini, the Andrews or the Girard unassociated with infection can be said to be practically always successful. Inasmuch as these accidental infections are usually traceable to the buried sutures, if by any means we can eliminate their use, we lessen chances of failures. In the case of non-absorbable sutures like silk or silver wire, it is not an uncommon experience to have a primary union and yet a year or longer afterwards to have a patient return with the auto-infection of a stitch successfully buried that length of time and requiring removal.

Whatever the method of operation, McEwen, Bassini, Andrews or Girard, the success of the operation is dependent upon the formation of a cicatricial connective tissue between the apposed surfaces retaining them where placed. McBurney's demonstration of the occasional unreliability of this cicatricial material as a resisting medium in hernia teaches us that occasionally we must expect failures because of this very yielding of connective tissue. Could we, however, by any means incorporate in such a cicatrix such white inelastic tissue as these tendons present, especially when interwoven as a running suture is, then we can certainly feel more confident of its permanency and unyielding character.

In very young children, and some women, the tendon of the external oblique is sometimes so poorly developed that I am convinced that this method of suture will not be applicable to every case, and have refrained from trying it under these circumstances. As to the tensile strength of strips of tendon of sufficient size for use as suture material, this can be said, that they withstand a tensile strain of from 11 to 24 pounds without breaking.

1. The number has since increased to twenty.

Sufficient time has not elapsed since any of my operations to state that the method is any more successful than with animal sutures. It is logical to conclude however, that if the identical technique is followed, using these living strips as is followed with aseptic animal tendons, and a primary union with normal convalescence is obtained, that if they die and be absorbed, they accomplish all that the foreign material does, while if they live (as experiment proves) it remains to offer permanent resistance to future stretching.

Experiments are now in progress by means of which, after the lapse of sufficient time, I shall study the histological changes, if any, which grafts of this nature may undergo, and hope to have the honor of presenting to this Section the findings.

DISCUSSION.

DR. C. A. POWERS, Denver—We all know how useful and popular is the modern operation for the radical cure of inguinal hernia, and every addition to our technic is welcome. Dr. McArthur has presented this simple matter in a very plain and modest way, and I personally believe that it is very well worthy of trial. I shall make use of it for I think it promises to be an addition to our methods.

DR. D. N. EISENDRATH, Chicago—I do not know whether the Doctor has had any children among those whom he has operated on. I tried it in a child and was surprised to find, in a boy of 10, the tensile strength of the aponeurosis of the external oblique, which suffices to close the hernial canal. The only trouble I had at that time was the method of closing the suture, which was afterwards explained to me by the Doctor as the splitting of the tendon and then separating the two ends to tie them together. That was the chief difficulty. Everyone is surprised at the great annoyance of having suppuration, and in these cases it is certainly a great addition to our technic, where we have animal tissue.

DR. J. R. EASTMAN, Indianapolis—With regard to the suture strip that Dr. McArthur splits off I would like to ask how it happens to be so much longer than the wound in the aponeurosis of the external oblique. I wish to ask further if he has encountered cases in which the aponeurosis was so thin and delicate that the edge was split off where he has applied this tissue as ligature material. The autoplastic suture has considerable breadth and must involve some splitting of the aponeurosis of the external oblique, as it is introduced to close the wound. It appears that there would be some danger in this direction, and I would be glad if the Doctor could throw some light upon this phase of the matter.

DR. G. F. SHIMONEK, Milwaukee—It seems to me that since these autoplastic sutures represent a tissue which, histologically, is rather of low vitality, as all white fibrous tissues are, their existence must be very greatly limited. In order to oppose the adjoining edges it is necessary to put these sutures on the stretch, thus devitalizing them more or less completely; the result will be a complete absorption of the sutures, probably in as short a time as it takes to absorb plain catgut. Having had no experience with this method I can only say that I imagine it inferior to silkwormgut, kangaroo tendon or formalized pyoktanin catgut, because those tissues upon which the permanency of our results, in hernia, depends, are composed of fibrous tissue which requires to be held much longer in close approximation than do structures of higher vitality.

DR. MCARTHUR, in reply—The strips have been exaggerated in length in the drawings. One knows the length from the anterior spine up to the external oblique belly. It is a good length, in some, as I said, even six inches. The strips again are represented as flat. That is a representation which is not found as soon as they are loosened. When they are loosened they roll up as catgut does, and therefore pull through as does catgut and do not make a long stitch wound in the edge of the external oblique any more than the catgut or any suture material does. The edge I have not found to tear out more than it does in using any other suture material. I recall one

case in which it did tear out. I want to report a case that was operated on by this method, in which a death occurred on the fourth day from a total suppression of urine. I want to report it, because it presented that rather rare type of hernia —necessitating a prolonged operation—because I did not recognize for some time I had to deal with what is spoken of as the "sacless hernia" *(hernie par glissement)*, made possible by the fact that in certain cases the anterior aspect of the colon is only partially covered by peritoneum; a large portion of its outer posterior aspect is uncovered by peritoneum. This sometimes slips down and presents in a hernial ring. When you cut down on the mass, you look in vain for a peritoneal covering; still you feel the gurgling within, find the contents of the bowel and know that you are close to it—you find no peritoneum; or until you pull it down, you do not find any peritoneum. It was so in this case, a man 62 years of age, who was a peddler, urging that he be operated on, because he had to jump down from his wagon and could not keep this hernia up with the truss. I concluded to operate, and he died, without any doubt from a too prolonged anesthesia for a man of his years; the total suppression of urine proved it, I think. It was not possible to get a postmortem. It was, however, possible in the night for my house surgeon to cut out the segment which had been sewed, showing the tendon *in situ;* microscopical sections of which are being made.

THE COSMETIC AND VISUAL RESULTS IN SQUINT.*

J. MORRISON RAY, M.D.
LOUISVILLE, KY.

Since Donders first promulgated the statement that strabismus convergens always depends upon hypermetropia, to the present time, the study of the etiological factor or factors concerned, has been one of ever-increasing interest; yet much still remains unknown and unsettled in our knowledge of this complex condition. A step was taken forward when it was proven beyond question that there must be a something besides hypermetropia to determine a squint. Schweigger, Stilling, Hansen-Grut, Wahlfors and others have attacked the subject, but no one theory explains all the features sometimes encountered.

The early age at which squint usually shows itself adds much to the difficulties of our gaining knowledge of the pre-existing conditions. The best way to approach the subject is by a careful study of cases. In doing this we often encounter phenomena that can not be explained by any of the ideas yet advanced.

Leaving to others a discussion of the theories underlying squint, I have chosen to address myself to a practical consideration of the visual as well as the cosmetic effect gained by the different methods of treatment. In order to do this I have selected 100 cases of convergent strabismus that have been under my personal care in private practice during the past four years. I have excluded all cases where a visible diseased condition such as corneal, lens or vitreous opacities of fundus changes were present. Each case has been under observation for several months, and a careful test of the vision made when possible; and the refraction determined either by subjective or objective tests under the influence of a cycloplegic (usually atropia).

The ideal result from the treatment of squint would be that which, while bringing about parallelism of the visual lines, would at the same time improve the vision in the defective eye, and produce binocular single vision in all portions of the field of fixation. Were these ends obtainable in all cases the chapter on squint could be closed. The studies and writings of Javal, Priestley Smith and others have aroused a fresh interest in the question of improving the vision in the amblyopic eye and lessening the squint by the so-called educative treatment.

Of the 100 cases selected for this study, 76 were cases of monolateral squint, in all of which the squinting eye was defective in visual acuteness; 24 were cases of alternating squint, in which the visual acuteness was practically the same in each eye. Of the 76 cases of monolateral squint, in 21 cases, or 27 per cent., who were old enough to answer to the subjective test, improvement in the acuteness of vision in the amblyopic eye was obtained by correction of the refraction. In these cases the vision was first tested, then a cycloplegic was instilled, and the correction ascertained both by objective and subjective tests. After adaptation of the correcting lens, which was as near as possible a complete correction, a test was again made with the pupil in its normal condition. The following results in the 21 cases were shown: 1 case was improved from excentric fixation to 14/200; 1 from 18/200 to 20/200; 4 from 20/200 to 20/100; 2 from 20/200 to 20/70; 1 from 20/200 to 20/50; 1 from 20/200 to 20/30; 2 from 20/100 to 20/70; 3 from 20/100 to 20/50; 1 from 20/70 to 20/50; 3 from 20/50 to 20/40; 1 from 20/50 to 20/30, and 1 from 20/40 to 20/30.

The amount of hypermetropia present was as follows: 2 cases with 1 D.; 3 with 2 D.; 7 with 3 D.; 5 with 4 D.; 2 with 5 D.; 1 with 6 D., and 1 with 4 D. of simple hypermetropic astigmatism. In 6 cases astigmatism of from 1 to 3 D. was combined with the hypermetropia.

The improvement obtained in these cases was always apparent shortly after the lenses were adjusted, and is, I believe, a result of the lessened eye strain due to the formation of a more distinct image on the retina brought about by an accurate correction of the refraction error, and not to direct improvement in the perceptive powers of the retina. This same improvement is often noted in one-sided amblyopia without squint where the hypermetropia and astigmatism have been corrected.

More recent writers seemingly having taken the cue from the authorities noted, have gone even farther, and now we almost daily read of cases of squint with high amblyopia and excentric fixation in which a correction of the defect in refraction and exclusion of the fixing eye has brought the vision of the defective one up to the normal standard of acuteness. Senn, in a recent article in "Wochenschrift für Therapie und Hygiene des Auges," reports ten cases in each of which the amblyopic eye improved under forced use, while in two of these the good eye deteriorated as a result of the exclusion. That isolated cases of marked improvement in amblyopia are encountered can not be denied. The reported cases of Johnson, Javal and others are conclusive, but in my experience I have not observed such results. One case where the amblyopic eye was forced to do the work of the former fixing eye has been under observation: A boy 16 years of age presented a squint of the right eye with amblyopia. A corneal ulcer produced a large central opacity on the left or fixing eye; the right then became the useful eye, and while under observation for six months the vision did not change from 20/70.

All will admit that when a squint is corrected, of scarcely less importance than improvement in the acuteness of vision in the amblyopic eye, is the attainment of

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

binocular single vision. It is a frequent observation that parallelism of the visual axes is obtained so that when distant objects are fixed, pictures of the object are focused on functionally corresponding points of each retina, and yet the power of blending these images into one is absent in the brain. The advocates of the early training of the squinting eye argue that the development of this fusional faculty is the keynote to successful treatment. In a majority of the cases of squint coming under observation the youthfulness of the subject precludes the possibility of such training. In order that this end may be accomplished diplopia must first be produced, and then the two images united; whether one eye be amblyopic, or the visual acuteness equal, the production of double images is difficult and sometimes impossible. Often in those in which it can be brought about it can not be maintained for a sufficient length of time to estimate the separation. The cases of alternating squint seem to keep up a constant shifting from one eye to the other, making it impossible to hold the double images.

The absence of the power of binocular single vision seems not to be influenced by the presence of amblyopia. In a large majority of alternating squints it is absent; on the other hand, in 50 cases of congenital amblyopia without squint observed, binocular fusion was present in 90 per cent. of the cases, but often high degrees of heterophoria were encountered. In only 7 of the 100 cases under consideration was I able to produce binocular blending of the images so as to gain the sense of perspective. Of these 7 cases 4 were alternating squints in which parallelism was produced by operation. This operation consisted in one case of tenotomy of both interni at intervals; in 3 cases tenotomy of one internus with advancement of the externus. The 3 remaining were monolateral squints in which binocular single vision was obtained by correction of the refraction by glasses, the amblyopia in the squinting eye was not extreme. In 5 cases only have I been able to get the patient or their parents to carry out the procedures advised by the advocates of the educative method of excluding the good eye for a number of hours daily. In only one of these was any apparent effect produced. This was a child of 3 years of age; the mother carried out faithfully for two years my instructions. There was present 6 D. of hypermetropia. Under glasses and the exclusion-pad used daily for several hours the vision improved from excentric fixation to 12/200, and the convergence lessened from a squint of 6 mm. to 2 mm. and the fixation has apparently become central. One other case watched carefully was a boy of 9 years, in which the parent insisted that the instructions had been faithfully carried out. After eighteen months the eye with excentric fixation remained in the same condition. The methods used were those advised by Priestley Smith: Exclusion of one eye, bar-reading and the stereoscope. The use of the stereoscope in my experience in children has not accomplished anything; and bar-reading seems to be of no value in alternating squint.

When studied from a purely cosmetic standpoint success in the treatment of strabismus offers much encouragement. In practically all cases we can expect to produce a lessening of the deformity by glasses or tenotomy. Glasses should always be given a thorough trial and no operation resorted to until all the effect possible has been produced thereby. Of the 100 cases under study the following are the results produced in lessening the deformity by accurate correction of the refraction: 43 cases showed a decided lessening of the convergence; in 60 per cent. of these, or 26 per cent. of the entire number of cases, the result was parallelism of the optic axes. Of these 26, 23 were monocular squint; 3 alternating. Therefore, the percentage of cases of monocular squint cured by glasses was 30 per cent., of alternating squint 12 per cent. The result of operative interference is shown as follows: 41 cases were operated upon; 12 cases, or 29 per cent. of parallelism, was obtained; 15 cases, or 36 per cent., were improved; 14 cases, or 34 per cent., were not improved. In 3 of these latter divergence eventually became apparent. Of the 24 alternating cases 15 were operated upon; 7, or 29 per cent., were cures; 5, or 20 per cent., were improved. In 2, divergence was eventually noted. In these cases no perfect cosmetic results were obtained by simple tenotomy of one internus. Division of both interni at intervals, or tenotomy of an internus combined with advancement of an externus was necessary to bring about the desired effect.

It has been my observation that in all cases of alternating squint there is a decided weakening of the power of abduction and that simple tenotomy does not lessen the squint more than 2 mm. Alternating squint seems to present a much more difficult problem to solve than does strabismus with one-sided amblyopia. A smaller percentage are relieved by glasses. Simple tenotomy of an internus produces a much more uncertain result, and fusion of the images of the two eyes is more difficult. If training the amblyopic eye in a monolateral squint, before first accomplishing parallelism of the optic axes, improves its powers of perception, we may transform a monolateral into an alternating squint; and as far as its correction is concerned the last condition of the patient is worse than the first.

From a cosmetic standpoint the ideal squint operation is that which will produce parallelism of the optic axes and leave behind no ugly depression due to the sinking of the caruncle at the inner canthus; nor limited motion of the eyeball when making excursions in different directions.

The statement that binocular vision is necessary to maintain the cosmetic result does not hold true. I recently examined a young man 23 years of age, with the following history: When 7 years of age he was operated upon for convergent strabismus by tenotomy of both internal recti. No glasses were ordered and no measurement of his visual acuteness undertaken. At the age of 12 years he came under my care; tests at that time showed great amblyopia in the right eye. Under atropia I found only 1 D. of hypermetropia in each eye. A few weeks ago I again examined him. There is no binocular vision. He wears +.50 D. S. each in close work. His eyes are parallel. The cosmetic result is good. The excursions of the eye are not restricted, and beyond a slight sinking of the caruncle in the amblyopic eye, no evidences of the former squint are apparent. He has taken a regular college course and is a scholar of recognized ability.

Some of the statements I have made may appear dogmatic and at variance with the opinion of others, but they are based entirely upon my personal observation and the knowledge gained from the cases chosen for study. Many other points were noted that have not been considered: such as heredity, and the frequent encountering of amblyopic individuals in the families of those who squint. Alternating and monolateral squints will be found indiscriminately in squinting families, showing

that there is an unknown something common to both forms. Spontaneous cures in squint are not as uncommon as we might expect. We can find such a history often in cases classed as congenital one-sided amblyopia. The following points, it seems, should be emphasized:

1. The effect gained in the treatment of strabismus, whether parallelism of the visual axes be obtained by a cycloplegic, glasses, orthoptic exercise, or an operation, is largely, or we might say, wholly cosmetic.

2. Glasses should be adjusted to the eyes of squinting children at as early an age as possible, depending upon the ability of the parent to control the child; and they should always be worn for a sufficient length of time to determine their effect upon convergence, before any steps in the way of an operation are undertaken.

3. The use of the exclusion-pad and orthoptic training are advisable, not so much in the hope of increasing the vision in the squinting eye, as to improve the power of co-ordination in the recti muscles, so that when the child reaches the proper age for operation the power of simultaneous muscle action will not have been lost.

4. Binocular single vision is not present in more than 7 per cent. of cases of squint, and its production in a larger percentage uncertain and unsatisfactory. Parallelism of the visual lines does not mean binocular single seeing.

5. Double images are not necessary for a successful issue. Cosmetic results can be obtained and maintained where the fusion power is absent. This is true in monocular squint with great amblyopia as well as in the alternating form.

6. Congenital amblyopia is often found in eyes that do not squint, especially combined with hypermetropia and astigmatism, and often in members of a family where squint in others is present.

7. In alternating squint if the hypermetropia is of a high degree the chances for producing parallelism are better than when the hypermetropia is low. In alternating squint with hypermetropia of a medium degree the necessity for an operation and the difficulties of producing parallelism by tenotomy are greater than in monolateral squint.

8. The effect of a tenotomy is greatly influenced by the amount of abducting power present in the corresponding externus. This should always be especially noted in the alternating variety.

9. Two tenotomies on the same internus is bad surgery, since it invariably leaves a sunken caruncle and later divergence.

10. From a cosmetic standpoint the correction by operation is not as simple as might be supposed. What is gained by straightening the eye, if there is left a noticeable exophthalmos with limited motion of the eye both outward and inward?

423 W. Chestnut Street.

Intermittent Pernicious Anemia.—Foustanos describes in the *Grèce Médicale* for June, a case of intermittent pernicious anemia. The hemolysis occurred for seven to ten days, and then seemed to be arrested for a time, while the tumefied spleen and liver retrogressed nearly to normal size during the intermissions. He accepts this case as evidence that pernicious anemia is not a disease of the blood-forming organs, but is the result of the action of some unknown toxic substance in the blood, occurring principally in the hepatic and splenic regions.

STRABISMUS; ITS TREATMENT.*

A. EDWARD DAVIS, A.M., M.D.

Professor of Diseases of the Eye in the New York Post-Graduate Medical School and Hospital; Assistant Surgeon in the Manhattan Eye and Ear Hospital, Etc.

NEW YORK CITY.

If some one were good enough, or I might better say wise enough, to formulate a uniform set of tests for the detection and accurate measurement of strabismus, to be used by all observers in order to compare the results or the different methods of treatment, we might arrive at some valuable conclusions as to the best treatment of this affection. Again, a better understanding of the physiological action of the ocular muscles and, indeed, of physiology in general than now, as a rule, obtains would help elucidate the intricacies of the subject. The anatomy of the ocular muscles has been gone into thoroughly, but the physiological action of the ocular muscles and their intimate relation and co-relation in the use and movements of the eyes has been overlooked, or at least not kept in mind, it seems to me. In addition to a résumé of the subject of the treatment of strabismus, therefore, I shall call attention to these two points in particular, to-wit: The different tests for strabismus, and the physiology relating to the subject. In addition also I wish to call attention to the Panas operation for strabismus with table of cases.

Physiology.—Of course, this paper is entirely too brief to go into extended observations on the physiology of squint, but there are two or three points of importance I wish to bring before you for consideration. Incidentally, I may say, I include the insufficiency of the ocular muscles under these remarks, because an insufficiency is nothing but a latent squint, which may be easily forced into a manifest squint by the use of prisms—a practice which, I am sorry to say, is followed by some of my American colleagues. If we are to obtain the best results in the treatment of strabismus, either manifest or latent, we must bring to bear a knowledge of the physiology of the muscles and nerves in general. for an insufficiency or weakness of an ocular muscle differs in no particular in a physiological way from an insufficiency or weakness of any other voluntary striated muscle. For it is a well-established fact of physiology that the nerve-cells give out before the muscles. "It is undoubtedly of advantage to the body," says Warren P. Lombard,[1] "that the nerve-cells should fatigue before the muscles, for the muscles are thereby protected from overwork."

Now, in an insufficiency or weakness of any ocular muscle, the specialist—the ocular-muscle specialist, in particular—is prone to forget this general and most important physiological fact, and begins to treat the muscle itself locally by prescribing prisms or performing graduated tenotomies of the opposing muscles, or some other equally absurd procedure; failing to recognize that it is the nerve-cells which are fatigued, weak and at fault and in need of treatment. And this treatment, in the main, should be through increased nutrition, by means of tonics, rest, outdoor exercise, and by local treatment. The local treatment should consist of the proper correction of the error of refraction, and by having the patient turn the eyes forcibly in the direction of the weak muscle or muscles several times a day. Perhaps the local exercise of the weak muscles by means of prisms for a

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

1. An American Text-Book of Physiology, 1900, p. 78.

few minutes at a time each day may be a benefit in some cases, especially in cases that have been operated upon. In my own experience, however, this has not been very satisfactory. The practice of prescribing prisms for constant wear, except in paralytic squint, or in case of anatomical insufficiency (due either to faulty development, insertion or enervation of the muscle) should never be followed, because the weak muscle is made weaker and the strong muscle made stronger all the time, until the latent squint is made a manifest one. I have seen this occur more than once. The gentlemen who prescribe prisms for constant wear for insufficiency of the ocular muscles, and do not follow them up with stronger prisms, and, finally, with graduated tenotomies of the opposing stronger muscles, do not follow their treatment to a logical conclusion. For it has been demonstrated innumerable times that prisms, when worn with their bases over weak muscles and their apices over the opposing stronger muscles, make the strong stronger and the weak muscles weaker. In fact, increasing the strength of these prisms every few days or weeks, to bring out the extra strength of the strong muscles is the very method pursued by the men who perform graduated tenotomies. The gentlemen who prescribe prisms for physiological insufficiencies should follow up the first pair with the second, and a third and a fourth, if necessary, and finally perform tenotomies, or abandon the practice altogether, with the exception above noted, that is, in anatomical insufficiency or in paralysis of the ocular muscles.

Neither the constant wearing of prisms nor graduated tenotomies are the correct treatment in insufficiency of the ocular muscles or latent squint, but general treatment as above indicated, together with the correction of the refractive error, is the more rational procedure. This is certainly a common-sense method, and assists in the restoration of normal physiological action to the muscles through increased nutrition to the nerve cells. In weakness of the ocular muscles, just as in weakness of the muscles in general, we should, as Lombard well says, "Always bear in mind that though 'beef' is of use to the athlete the muscles are merely the servants, and can accomplish nothing if the master is sick. The nerve cells always give out before the muscles, and the man preparing for a contest should watch his nervous system more than his muscles."*

If the treatment of latent squint by means of prisms and graduated tenotomies is of little practical value, how much less so is the treatment of manifest squint by these means. In fact, the treatment of manifest squint by means of prisms, or by graduated tenotomies, has been abandoned by most oculists, and, at most, is but a sad memory to those who have tried it.

TESTS FOR STRABISMUS AND THEIR RELATIVE VALUE BEFORE AND AFTER OPERATION.

Perhaps the most important step in the treatment of any disease is finding out the exact nature and extent of the disease; in other words, properly diagnosticating the disease. We have a number of tests for measuring squint, its nature and amount more or less exactly; but unfortunately, many of these tests can not be used in very young subjects, a class in which the majority of squint cases are observed. I shall describe at this point the principal tests for squint and their method of application, and after that give the technique of a routine examination bringing into requisition the different tests in the order of their importance, hoping thereby to establish what might be termed a standard examination for strabismus. Of course, this routine examination should not be made in exactly the same manner in every case, as there will be exceptional cases and individual peculiarities that will demand a modification to a greater or less extent of the method. But this routine examination should be followed as closely as possible in every case if we are to have a standard by which to compare the results of different treatments, and ultimately to select the best method of treatment as found out by this method of comparison. Uniformity of tests in these cases of squint is all important.

1. In latent squint or ocular insufficiency, the most reliable test in my experience is that made with ordinary prisms for adduction, abduction and sursumduction, etc., as follows:

To obtain the power of adduction, have the patient look at a candle-flame 20 feet distant, with both eyes open and any refractive error he may have properly corrected; then begin the test with the one degree prism, apex inward, that is, toward the nose and increase the strength of the prism until the patient sees double. The strongest prism he can overcome without seeing double measures his adduction.

The abduction is obtained by placing the apex of the prism outward toward the temple, and gradually increasing it till the patient sees double; while the sursumduction right and left is obtained by placing the apex of the prism upward in front of the right and left eye respectively, and increasing the strength till the patient sees double.

J. M. Bannister, in testing 100 soldiers with normal eyes, found the average adductive power to be 14.1 degrees, abduction 7 degrees and sursumduction 2 to 4 degrees, the relative strength of adduction to abduction being two to one. Any wide deviation from this relation, especially when asthenopia is complained of, should be considered as an insufficiency and should receive treatment as indicated in the first part of this paper.

2. The Maddox-rod test for muscle insufficiency is practiced by many oculists, but in my experience it is not as reliable as the simple prism test. Besides, it has the same fault as the old Graefe test for muscle insufficiency, that of causing a diplopia as the first step in the test for insufficiency. This is a serious mistake as it takes away from the eye the stimulus for fusion of the images.

There are a number of tests for manifest squint, the principal ones of which I shall now describe:

1. *Perimeter Test.*—This is the best test for squint that we have, but unfortunately it can not be used accurately on patients under 5 or 6 years of age. As the majority of all squints are of a convergent nature and as about 40 per cent. occur in children under 6 years of age, it will be seen what a serious handicap this is. This test is made as follows:

Place the patient at the perimeter with the squinting eye in a line with the center of the arc, which should be in the horizontal position; have the patient look directly in front of him at a light or some small bright object 20 feet distant. Now carry a lighted candle along the arc of the instrument until the image of its flame occupies the center of the cornea of the squinting eye. Read on the arc the number of degree the candle is from the center of the arc. This is the degree of the squint. For example, say the candle is carried to the twenty-degree mark on the arc when the image of its flame occupies the center of the cornea of the squinting

*Loc. cit., p. 76.

eye. Twenty degrees is the amount of the squint, convergent or divergent as the case may be.

In vertical squint the arc of the perimeter should be placed in the vertical meridian, and while the patient looks in the distance the candle should be carried along the arc from its center until the image of its flame occupies the center of the cornea of the deviating eye. The position on the arc at which this happens indicates the amount in degrees of the squint.

To get the amount of the squint for the near point have the patient look at the center of the arc and move the candle along the arc in exactly the same way as before as in testing for the distance. The position on the arc at which the image of the candle flame occupies the center of the cornea of the squinting eye measures the amount of the squint. I have found the amount of the squint for the near point, in convergent squint, as a rule, to be two to five degrees greater than for the distance, due perhaps to an act of the accommodation.

2. *Cover or Screen Test.*—Have the patient look in the distance at some small object, as a candle flame; stand in front of the patient with the head lower than the patient's so as not to obstruct his view, cover the patient's good eye with a card and have the patient fix the candle flame with the squinting eye. Now place the strabometer of Laurence against the lower lid with the zero mark on a line directly under the center of the cornea of the uncovered eye; then remove the card from the good eye, when the patient will fix the candle with it and squint the bad eye as usual with him. Note on the strabometer the number of lines the center of the cornea of the squinting eye has moved from the zero mark. This gives the angle of the squint. The advantage of this test is that it can be applied in very young children.

3. Priestley Smith's *Tape Measure Test.*—This consists of two pieces of tape, one black and one colored, each one meter in length, and attached to a ring which can be slipped over the thumb. The colored tape is divided by lines into twelve parts, and numbered 5, 10, 15, etc., up to sixty degrees, ending in a small weight to keep it taut during measurements. The patient holds the end of the black tape against his face directly under the squinting eye, while the observer stands directly in front of him with the ring attached at the other end of the tape over his thumb or ophthalmoscope which he holds in front of his eye. The patient looks directly into the ophthalmoscope from which a light is reflected into the squinting eye. It will be noted that the image of the light from the ophthalmoscope will be to the other side of the center of the cornea in convergent squint and to the inside of the center of the cornea in divergent squint. The observer now takes hold of the colored tape at the ring, the edge of the hand being held towards the patient for the patient to look at, and lets the tape slide between his fingers, carrying it in a direction opposite to that in which the eye squints. Both eyes should follow the hand, and when the squinting eye has turned sufficiently for the image of the light from the ophthalmoscope to occupy the center of the cornea in that eye, stop the hand and note the distance it has moved along the tape. The number on the tape indicates the degree or angle of the squint.

This test is accurate enough for all practical purposes, and if the angle alpha is taken into account it is quite reliable. Then it has the great advantage that it can be used on very young children.

4. *Hirschberg's Test.*—This test consists in estimating the angle or amount of the squint from the position of the image of the candle flame reflected from the front of the eye. The candle is held about one foot in front of the patient who has both eyes open. The image of the flame in the eye that fixes will be in the center of the cornea, while the image on the squinting eye will be more or less eccentric according to the amount of the squint. With the average-sized pupil, 3.5 millimeters, if the image is half way between the center of the pupil and the pupillary margin the squint is less than 10 degrees; if at the pupillary margin, 12 to 15 degrees; if midway between the margin of the pupil and the corneal limbus about 25 degrees; if at the edge of the cornea 45 to 50 degrees; if out on the sclera 60 to 80 degrees.

Of course the angle alpha should be taken into consideration in this test. This test is not very accurate but sufficiently so for practical work. It has the great advantage of application in very young subjects.

5. *Linear Measurement Test.*—This test is to be recommended only in case of false fixation. Have the patient look directly in front of him with both eyes open at a small object in the distance. Mark on the lower lids with ink a dot on a line with the outer border of the corneæ. Then measure the distance of the dots from the outer angle of the eye on each lid respectively. The difference in millimeters gives the amount of the squint.

6. *Prism Test.*—This test is applicable in those cases only where binocular vision exists. In recent cases where this condition sometimes obtains, and in cases where binocular vision has been brought about by treatment through improvement of the vision in the amblyopic eye and by bringing the images in the two eyes closer together (to get which latter condition this test itself is often employed), the prism test is of much value. It is applied as follows: Have the patient look at a candle flame 20 feet distant. Note the nature of the diplopia, if homonymous, cross or vertical; or if a combined deviation, by placing a red glass in front of one eye—the better one. In fact, it is often necessary to put a colored glass in front of one eye in order to establish a diplopia. Where the diplopia is present without a colored glass in front of the eye, the colored glass should be removed after the nature of the diplopia is established. The strength of the prism that is necessary to bring about single binocular vision divided by two represents the amount of the squint. For example, say we have a horizontal homonymous diplopia and that it requires a 20-degree prism apex inward to produce single binocular vision. This shows a convergent squint of 10 degrees. Again, say we have a horizontal cross diplopia which requires a 20-degree prism apex outward to cause single binocular vision. This shows a divergent squint of 10 degrees.

For establishing the fact whether single binocular vision does or does not exist, the prism test is invaluable. It is not altogether reliable as to the amount of the squint, exaggerated amounts being shown by it as compared with the perimeter test. I have seen the perimeter test show a squint of 10 degrees and the prism test immediately—in the same case—show 25 degrees. The cover or screen test also often gives an exaggerated amount of squint as compared with the perimeter test, especially in those cases where the squint is almost corrected and where binocular vision is present. There is a stimulus and a desire for fusion of the images in these cases, and when the screen is placed in front of one eye it at once eliminates this factor, and the result is the deviation of the eye behind the screen—to an exaggerated degree. With the perimeter test

both eyes are left open and the desire for fusion of the images is not disturbed, and a more correct test is possible. Therefore, in every case where the perimeter test can be made it should be used in preference to any other test.

Hirschberg and Landolt have charts to hang on the wall by which the angle of the squint can be measured, but they are of service chiefly in paralytic squint (which is not under consideration in this paper), and in squint cases where binocular vision exists. In ordinary strabismus these tests are not very satisfactory.

The above tests should be tried in the order given, the perimeter test in all cases where it can be used, the screen test, the tape measure test, prism test, etc. Two or more of them at least should be tried, in order to ascertain accurately the amount of the squint.

NON-OPERATIVE TREATMENT.

This consists in the use of atropin, atropin and glasses, the exclusion pad, the stereoscope, and bar-reading. It should be tried in every case of strabismus before any operation is undertaken, and should be continued in as long as the squint continues to improve. When improvement ceases by this method then it is time to operate. The different steps of the non-operative treatment are as follows:

1. *The Exclusion Pad.*—This consists in tying a patch over the good eye in order to make the patient look at objects with the squinting eye, which usually has poor vision, especially if the squint is constant, unilateral and of long duration. In this way the patient does not lose the faculty of locating or fixing objects with the squinting eye, and at the same time maintains and develops to a marked degree in some cases, as above quoted, the vision in the squinting eye. In cases of alternating squint, that is, where the patient first uses one eye, then the other, the faculties of vision and fixation are usually good and equal in each eye, being maintained as I believe simply by the use of first one eye and then the other. Therefore, following the plain lesson set by nature in these cases of alternating strabismus, we should, in cases of constant unilateral strabismus, where they can not or will not voluntarily use first one eye and then the other, make them do so by excluding the good eye from vision with a pad a certain number of minutes or hours each day.

2. *Mydriatics.*—A mydriatic, usually atropin, is used in the treatment of strabismus in order to paralyze the accommodation, and indirectly to act on the convergence. For, anything that relaxes the accommodation, relaxes at the same time and within certain limits the converging power of the eyes, the connection between the two functions being intimate.

The strength of the solution of atropin to be used depends on the age of the patient. In young children one-half to one grain to the ounce solution is quite strong enough. In older children (over 4 years of age) two to four grains to the ounce solution may be used. The parents are to be cautioned as to any poisonous symptoms of the drug, as flushed face, dry, hot skin, and dryness of the throat, and instructed to stop its use if these symptoms appear. Where an idiosyncrasy exists for the drug it can not be used at all; then some other mydriatic, as duboisin, must be substituted. One drop of the solution should be instilled into each eye twice a day and this to be kept up for one month, when it should be intermitted for that length of time. This should be repeated two or three or even four or five times according to the progress of the case. In divergent strabismus, atropin is contra-indicated, but may be used to ascertain the refractive error after which it should be discontinued.

3. *Glasses.*—Glasses help to correct convergent strabismus in two ways: 1. They improve the vision by correcting the refractive error, especially if astigmatism is present, if the squint is not of too long duration. This gives a stimulus to use the eyes together. 2. The glasses, by taking the strain off of the ciliary muscle, lessen convergence in exactly the same way as mydriatics do by relaxing the accommodation. Many cases of convergent strabismus are relieved by the use of atropin and glasses alone if taken early. And, if the exclusion pad is used in addition, it greatly increases the chances of recovery without operation.

Usually in fitting glasses I do not use a mydriatic of any kind, but in strabismus cases I always use a mydriatic, because it helps directly to improve the squint and at the same time allows almost full correction to be given the patient to wear; not only this, but as most of these cases are under 6 years of age and can not be tested subjectively, that is, by the trial case and test card, it makes the objective test easier and more accurate.

When divergent strabismus is present in hypermetropic eyes, no glasses should be worn except to correct any astigmatism that may be present, because by relaxing the accommodation they increase the divergence. In myopia and myopic astigmatism the refractive error should be corrected fully, for the minus glasses stimulate the accommodative act, and in this way increase convergence and help overcome the divergence, especially in low degrees of divergence.

4. *Bar-Reading.*—In patients who are old enough, bar-reading is a useful adjunct in making the patient use the eyes together. It consists simply in holding a pencil or some other small object vertically before the eyes, and in front of a page of printed matter which the patient is reading. If the patient is not using the eyes together, but only the good one, when the line of vision in the good eye comes to the pencil the patient will stop reading or skip a word, or part of it, whereas, if the eyes are being used together, no such stop will take place, or missing any letter or part of a word. By persistent practice with this method the patient is often brought to use the eyes together, with effort at first but with facility after practice.

5. *Stereoscope.*—The stereoscope can not be used till the patient is 5 or 6 years of age. Its use gives the greatest stimulus to single binocular vision, that is, true form perception. By using special pictures, especially geometrical figures, as truncated pyramids, the idea of perception of form in three dimensions is given.

There are a number of stereoscopes of special make to be had, but the ordinary stereoscope as bought in the market, if the prisms are removed and plus 6 D. spherical glasses substituted, answers all the purposes for the stereoscopic exercises. Especially is this so if the pictures of Dr. Kroll are used. These can be bought at any good optician's, the whole outfit, stereoscope and pictures, costing but two or three dollars. The patient should be instructed how to use it at the office, then should purchase one to be used at home. There is one sliding picture among Kroll's pictures. For fusing purposes this is admirable. At first the two sides can be brought close together until the eyes are able to fuse them as one; then the distance between them increased until the eyes are brought parallel, or almost so, and still fusing the images. This should be done for

a few minutes at a time several times a day, the muscles not being exercised at any one time to the point of exhaustion.

OPERATIVE TREATMENT.

There is a wide difference of opinion among surgeons as to the best method of operating for strabismus, also as to the proper age to operate. Individually, I think no operation for strabismus, with few exceptions, which I shall presently state, should be performed on children under 4 years of age. I am aware of the fact that not a few operators have operated for a strabismus as early as 2 years of age. This should not be done, but on two conditions: 1, where the squint is congenital, constant and not improved by the exclusion pad and atropin; 2, where false fixation exists. In the first condition I believe the squint is due to fault in the muscle itself, that is, improper development or insertion; and in the second, to marked amblyopia, which is not likely to improve by non-operative measures, but to get worse by delay. After 4 years of age, the proper time to operate is when the non-operative methods cease to improve the condition of the strabismus, but not under six months' time should be considered a fair trial in any case of the non-operative treatment, unless some special reason prevails.

The different operative procedures for the correction of strabismus may, in a general way, be divided into four classes. The technique of individual operators may vary to some extent, but the essential part of the operation remains the same.

1. Simple tenotomy of one muscle in the deviating eye, and later if effect enough is not obtained to perform advancement of the opposing muscle in the same eye.

2. Simple tenotomy of one muscle in the deviating eye, and later, if not enough effect, tenotomy of the like muscle in the opposite eye; if still not enough effect advancement of the opposing muscles first in the deviating eye and then in the opposite.

3. Advancement of the weak muscles in each eye (the external recti in convergent squint and the internal recti in divergent squint), after Landolt's method.

4. Stretching the strong muscles in each eye (internal recti in convergent squint and the external recti in divergent squint) and then tenotomy, after Panas' method.

Various devices for increasing or diminishing the effect of the operation have been recommended, such as a thread extending from one eye to the other and tied across the nose (Gruening) in cases of divergent squint; or a thread extending from the eyeball to the outer canthus in convergent squint after the operation has been performed. But these are only refinements of technique, and may or may not be used according to the desire of the operator.

In the first method of operating, where but one eye is operated upon, the assumption is that squint is a unilateral affection, and, therefore, the operations are confined to but one eye. I believe but a few members only of the profession follow such a procedure now, it being generally conceded that strabismus is a bilateral affection and not a unilateral one. Operations on one eye alone, therefore, should be discouraged, because they are performed under a misconception of the true nature of squint.

The second method of operating is followed by many surgeons, perhaps the majority of operations for strabismus come under this class. The method of performing an ordinary tenotomy is so simple that it needs no description here. Suffice it to say that the effect of a tenotomy may be materially increased or diminished by the extent of the dissection of the capsule of Tenon at the time of the operation. The wider and deeper the separation of the capsule the greater the effect, and vice versa.

The third method of operating was recommended by Landolt many years ago. He advised advancement of the weak muscle in each eye without tenotomy of the opposing muscle.

Of all the different advancement operations, I like best what is known as the straight advancement. It is as follows:

Make a vertical incision about one-half inch in length in the conjunctiva, about one line from the margin of the cornea and just in front of the attachment of the muscle to be advanced; dissect up the conjunctiva from over the tendon of the muscle, then make a small hole in the capsule of Tenon and introduce a hook under the tendon of the muscle, and then a second hook, and expose the tendon of the muscle for about one-half inch by pulling the hooks in opposite directions. Remove one hook while one is left to hold the tendon away from the eyeball so as to introduce three needles with thread attached—in each instance from without inward through the tendon of the muscle about one millimeter or more, according to the effect desired, from the attachment of the tendon—one needle at the upper margin of the tendon, one at the lower, and one through the middle of the tendon. The conjunctiva may be picked up on the needles just before they are inserted into the tendon of the muscle so as to advance it along with the tendon. The tendon is now cut from its attachment. The center needle is inserted into the sclera about two millimeters from the corneal margin, directly forward from the old attachment of the tendon, coming out at the corneal limbus. Then the needles in the lower and upper margins of the tendon are respectively inserted into the sclera below and above and on a vertical line with the central suture. The center suture is tied first, the lower and upper ones at the same time (one by an assistant) so as not to cause torsion of the eye.

Both eyes should be bandaged for fifteen hours; after which time it has been my practice to remove the bandage permanently, putting on iced cloths 10r one-half hour four times a day to relieve the congestion. In convergent squint if there is an under-effect I instill atropin and have the patient wear glasses; if an over-effect, I leave off the glasses and do not use atropin. Landolt advises to keep the eyes bandaged for a week, the patient in bed and quiet. Dr. Wooton, at the Manhattan Eye and Ear Hospital, who does essentially the same operation as Landolt, follows his plan of keeping the eyes bandaged for a week. Dr. Wooton reports favorable results from fifteen operations, only two being failures. My experience with simple advancement, without tenotomy of the opposing muscle, is limited and unfavorable. In no case was the effect sufficient. In a recent discussion of this subject at the New York Academy of Medicine, Dr. Gruening said he had tried Landolt's method, and had put cases at Dr. Landolt's disposal when he visited this country, but that in none of the cases was the effect of the operation sufficient. The ultimate results by this operation are not satisfactory because of not enough effect.

The fourth method of operating is after Panas' suggestion. He operates on both eyes in every instance. In convergent squint on the internal recti, in divergent

squint on the external recti. The tenotomy is performed in the usual way with this important variation, that the muscle to be operated upon is stretched before cutting. For example, in convergent squint the hook is placed under the tendon of first one internal rectus and then the other, and the eye turned forcibly outward until the cornea is entirely hidden under the external canthus, then the tendon is separated as in ordinary tenotomy. In divergent squint each external rectus is stretched by turning the eye forcibly inward till the cornea is hidden under the internal canthus, then simple tenotomy is performed. Both eyes are bandaged for twelve to fifteen hours, when the bandage is removed and iced cloths applied. In convergent squint, if the effect is insufficient, atropin is instilled and glasses then worn; if over-effect, glasses are left off and no atropin used. In divergent squint, if under-effect, glasses are put on; if over-effect, glasses are left off and atropin instilled.

The immediate result, as a rule, after a Panas operation is an over-effect, varying from five to twenty-five or thirty degrees. This rapidly disappears, however, till within a few days to a few weeks, in exceptional cases months, the eyes become parallel, and in the great majority of cases remain so; many of the cases securing single binocular vision by one operation.

To any one performing Panas' operation for the first time the immediate result is somewhat alarming. I must confess I was reluctant to undertake the operation until I saw the good results obtained by Dr. Roosa in eyes operated upon by this method. Especially was I fearful of over-effect in small degrees of squint. My experience with the operation, however, has taught me, contradictory as it may seem, that in low degrees of squint we are not so apt to get over-effect as in the higher degrees. It was puzzling to me at first to get a satisfactory explanation of this effect—opposite to what was naturally to be expected. After observing a number of cases and investigating the physiology of muscle and nerve stretching the following explanation was suggested: In cases of very marked squint, especially where there is a false fixation, with limitation of motion, where there is contracture and actual shortening of the muscle, the force that it requires to stretch such a muscle until the cornea is hidden in the opposite canthus is considerable, and the nerve fibers and muscle cells may be stretched to such an extent as to cause temporary paralysis, which it may take days, or, in exceptional cases, weeks or months even to recover from. On the other hand, where there is but a small or moderate degree of squint, the stretching does not have the paralyzing effect to near the same extent as in cases with excessive squint.

W. P. Lombard, in speaking upon the irritability of nerves and muscles, has this to say: "The irritability of muscles is likewise increased by moderate stretching and destroyed if it be excessive. Surgically, the stretching of nerves is sometimes employed to destroy their excitability. Slight stretching heightens their excitability, and even quite vigorous stretching has only a temporary depressing effect unless it be carried to the point of doing positive injury to the axis-cylinder and of causing degeneration. As nerves have the power to regenerate, they may recover from even such an injury."*

Again, in relation to the conductivity of the nerves and muscles, Lombard says: "The power of conduction appears to return before irritability, and may be observed first at the end of the third week. Apparently sensation is recovered before the power of making voluntary movements; this difference may well be due, not to any essential difference between sensory and motor fibers, but to the fact that extra time is required for the motor fibers to make connection with the muscles."

It is unnecessary to say that some judgment must be used in determining the amount of force to be used in stretching a muscle. If the cornea can not be hidden in the canthus without causing actual damage to the muscle fibers then it should not be carried so far. Of course, experience here, as in every other operation, counts for much in the successful result. Panas tested the strength of the ocular muscles thoroughly on the dead subject before performing the operation on the living, and found that the muscles could withstand great strain before breaking. Another factor in producing an over-effect in cases where excessive squint exists is the marked amblyopia usually present in such cases. The desire for fusion of the images is not so great in such cases as where the vision is nearer equal in the two eyes, as it often is in lesser degrees of squint. This factor, however, figures in the results obtained after any method of operating for squint, and is not peculiar to Panas' method.

In the cases which have not been successful after Panas' operation, over-effect has not resulted much more frequently than under-effect. Neither has the fear of ultimate over-effect, as predicted by the opponents of the Panas operation, been fulfilled.

There is one other operation of which I have not spoken so far, because I have had no experience with it. This is the knuckling operation of Savage and Valk. In the operation the muscle to be advanced, the weak one, is bared of conjunctiva and capsule of Tenon for some distance back of its attachment. Then a small speculum (Valk's), somewhat like the ordinary lid speculum, is placed under the muscle. A threaded needle is then so introduced that when the thread is drawn taut a knuckle is formed in the tendon, thus shortening the muscle. A longer or shorter knuckle is taken in the tendon according to the effect desired. When the effect is not great enough, Dr. Valk, I believe, performs simple tenotomy of the opposing muscle. Valk claims 100 per cent. of cures by this method, that is, parallelism. I think this too large a percentage to claim for any operation, as no operation yet devised to correct squint has proved entirely satisfactory. Individually, I prefer Panas' method to any other, and believe it will win for itself a permanent place in ophthalmic surgery.

(To be continued.)

* Loc. cit., p. 78.

THE REQUIREMENTS OF MODERN SURGERY.*

J. H. CARSTENS, M.D.
DETROIT, MICH.

Fifty years ago the surgical operations performed were principally amputations of limbs and operations for hernia and stone, but with the discovery of chloroform and ether and the resulting painlessness of operations, more surgery was practiced. During the next twenty-five years the resulting large mortality in all kinds of operations, even the most simple, prevented patients from submitting to them; yes, even the medical profession would only have recourse to them in extreme cases, and by this very procrastination the mortality

* Read at the Meeting of the Michigan State Medical Society, May 15, 1901.

was larger, to the odium of surgery, and the dread of it was manifoldly increased.

A quarter of a century ago, when Lister called attention to the frequent failures and causes of death after surgical operations and how to prevent them, surgery received a big impetus. When it was clearly demonstrated that wound infection was the trouble in most cases, and preventing wound infection by means of antisepsis, surgical operations could be performed with comparatively little danger. Then the surgeons became bolder and newer fields were opened for surgery; and as we advanced from antiseptic to aseptic surgery, that is to say, instead of killing or destroying the micro-organisms, we prevented them from getting into the wound, another great advance took place. This took another ten or fifteen years to thoroughly understand. So that we might say that modern aseptic surgery has only been practiced for the last ten years, and what a gigantic stride it has made during that time.

If you ask what is modern surgery, I would answer that it is the gospel of cleanliness; that covers the ground. But surgical cleanliness is entirely different from what the laity calls clean; it must be absolutely clean, and some great surgeon has placed in his operating-room a sign which reads: "Nothing is clean that can be made cleaner." Here we have it: Absolutely clean. There must be no dirt or foreign substance come in contact and infect the wound, and here is where the great difficulty lies, the almost impossibility of excluding all kinds of dirt. When we speak of dirt from a surgical standpoint we mean micro-organisms, infection, or the entrance of something into the wound which may cause suppuration, putrefaction, etc.

During the first years following Lister's investigation every effort was made to destroy the micro-organism by chemicals. Then an effort was made to sterilize the air with carbolic sprays, and great attention paid to prevent post-operative infection of the wound by covering the cut extensively with bandages and pads that were impregnated with chemicals. In the course of time, however, it was found that some of these chemicals were injurious and a better way would be to exclude germs instead of destroying them. Thus a gradual change took place, and from the antiseptic surgery we have come to practice aseptic surgery; that means the prevention of wound infection by absolute sterilization of everything coming in contact with the wound.

Here the problem comes and the difficulties, and here also failures are manifested on account of our utter impossibility of absolutely preventing infection in every case.

THE PATIENT.

1. The great point in connection with this is the individual to be operated on. In the course of time we have found that there are people who are immune against certain diseases; they have a power of resistance. Some person has it, say, against smallpox; others have it against measles. In the southern part of the country many have it against yellow fever. Some have this immunity against certain diseases some time during their life, and then another time they have not. Some seem to have it against one or a number of diseases, and others are so fortunate as to have it against a great many diseases. Yes, everybody has a power of resisting diseases in his own system, but the power is different in each individual. But in the present state of our knowledge, by looking at a person, by feeling his pulse or taking his temperature, we are not able to say in a given case how much power of resistance that individual has. We can to a limited extent judge by the history of the case and the general condition of the patient, and, in fact, we try in many cases by proper alimentation and treatment to increase the individual power of resistance to infection before we operate on them.

All these are intricate and complicated problems of surgery, and still how much greater is the difficulty in the real operation when we consider, as above stated, the absolute cleanliness. Every layman can see how very difficult it is to carry that out. First the patient himself is very difficult to clean, because the skin, the hair, the nails are swarming with micro-organisms of some kind, and in hundreds of experiments that have been made to clean the skin it has been impossible to do so absolutely, and in the present state of our knowledge comparative cleanliness has been the best we have been able to do. We have minimized the chances of infection of the individual himself. There is another point in connection with it; we have found that the danger of infection is in proportion to the amount of infection; in other words, a person is liable to resist the onslaught of a few micro-organisms in the wound; he can take care of them and destroy them, but when the number is large the powers of the body can not compete. It is like giving a person a teaspoonful of alcohol, which would not affect him very much, but if you give him a half pint, he would be drunk, and if you gave him a quart it would kill him. So that as far as the patient himself is concerned, we are able to get him or her reasonably clean.

THE HOSPITAL.

2. If the patient is clean you can not operate on him that way. The patient must be covered, kept warm, in fact. Some times a great deal of artificial heat is required during the operation to lessen the danger of shock, and, consequently, the patient must have clothing, blankets and covering of all kind. But all these are liable to be dirty. All these may look clean in a household, and the housewife may be the cleanest of women. Everything about the house and clothing, the linen and towels, may be neatness and cleanliness itself, and still all these are liable to be infected and to contain micro-organisms of all kind. That they do has been proven many a time; but this need not frighten anybody. This does not injure or endanger anybody in ordinary everyday life. But with the surgical eye we can see that wound infection can take place, and that it is dangerous to use such clothing, towels and sponges around a surgical case.

We insist on absolute sterilization of everything that the patient has on, of everything that is in the operating-room; this includes tables, chairs, all the basins and bowls and everything that may be used. Everything must be so clean and as clean as the patient is, and as clean clothing as he or she has on. All must be clean; the nurses, who are in attendance, the surgeon and his assistants, and everything that can by the remotest possibility come directly or indirectly in contact with the wound must be clean. The air is liable to carry contagion, although it has been proven that there is comparatively little danger of contamination from the air; but the air can be purified by gases, superheating steam, etc., if necessary, which will seldom be the case.

Considering all these points about the requirements

of modern surgery, anybody can readily see the utter impossibility of carrying out modern aseptic surgery in a private house. Simple little operations where the danger of infection is small, or rather if infection should take place, may delay healing and retard a rapid recovery of the case, but the patient's life is not jeopardized. Thus, simple operations can be performed, of course, in a private house. There will also be severe cases where the patient can not be moved, desperate cases where time is an object and must be subject to immediate operation, which will necessitate their being operated on in their own homes. Certainly, such emergency cases, operated upon at their own homes naturally have their chances for recovery lessened. The mortality in a hundred given cases would be greater than a hundred given kind operated under more favorable surroundings.

If a patient would die in 6, 12 or 24 hours, under all circumstances, he had better be given the benefit of operation at the house, even if the mortality in such cases would be 20 per cent., while in a hospital perhaps only 5 or 10 per cent. No one would think of letting a patient die without trying, simply because all the requirements of modern surgery are not at hand. In fact, even in a private house a great deal can be done in carrying out modern surgery. Clothing can be sterilized in an oven. In other cases micro-organisms can be destroyed by boiling, by soaking them in various chemicals, etc.

Every surgeon understands that what I want to call attention to simply is that the highest and most perfect type of surgery—that is, in the direction of the preliminary preparation of the patient, if that is necessary—the technic, the rapidity of the operation, the lessened danger from shock and the most careful judicious after-treatment of surgical cases can be better carried out in a well-equipped hospital than they can in a private house.

Naturally you will say that there are hospitals and hospitals. This is true, but a hospital need not be large and expensive as long as it is well equipped with the necessary apparatus for sterilizing, well equipped with trained nurses who are enthusiastic in the gospel of cleanliness, and as long as the surgeon is thoroughly competent. I have seen small hospitals in small towns where all the facilities were at hand and the best work was being done.

But here, like everywhere else, the great question of individuality has first place. It depends on the individual who is at the head of it, who manages and who directs it. A good disciplinarian and progressive up-to-date person is required. Otherwise a hospital that should be good may be no better, in fact, not as good as the home of an individual. In a hospital there must be facilities of strictly separating all infectious and contagious diseases from surgical cases.

THE SURGEON.

The third great requirement of modern surgery is the surgeon himself. Although I mention this last, it is not the least; in fact, it is really the principal requirement. The question of individuality always comes to the front, and the power of adaptation to environments of an individual is far greater than the power of environments to shape the course of a person. A patient in perfect health, with the greatest power of resistance, the most beautiful hospital, or the most perfectly arranged operating-rooms, the well-trained nurses and the alert assistants can not compensate for a poor operator.

Before the days of anesthetics there were few great surgeons, because great dexterity and perfect knowledge of anatomy was required. The surgeon in those days was a mechanical genius who had great dexterity, who had to operate very quick; every move had to count; every movement tended to do the operation rapidly; the pain and suffering of the individual was indescribable; it had to be shortened as much as it lay in human power. The slow and slovenly bungling operator did not exist; he soon dropped by the wayside and gave up surgery.

When anesthesia was used and the patient was free from pain, slower and more careful operating was allowable, and, in the course of time, this tendency to slowness and deliberateness has crept into the ranks of surgery more and more. Every slow and slovenly physician who never did any mechanical work in his life, whose hands are like an elephant's foot, whose joints are as stiff as a 30-year-old cow's, considers himself a surgeon, competent to practice surgery. So it has kept on, and to-day with modern clean surgery and the wonderful result and the consequent lessening in mortality, it is still worse.

When it is known how large a number recover after operations, every tyro thinks he can do the same thing. He perhaps sees a surgeon operate from a distance, sees how quick and easy it is done; and thus forthwith he rushes in "where angels fear to tread." He does not see the years of practice and experience that were required; he does not notice a thousand and one details of an operation; he does not see all the preliminary preparations.

In the first place he is a poor diagnostician; he will operate on cases that he should not operate upon; he will operate on them when they should not be. In cases that need operation, he hesitates, he trembles, and the "golden moment has escaped." Many men just out of college rush out to operate, and the more difficult the operation the more anxious they are to do it. They have seen operations from their seats and know a little anatomy; forthwith they are surgeons. Some old practitioners who have practiced a quarter of a century or more, hearing about the wonderful results and the great fees received by surgeons in the medical centers, forthwith buy a new edition of surgery, read up and proceed to operate. Fortunately, some of these, after they have killed a dozen people, see the error of their ways, give up and return to practice. If anyone should hint to these people that they are not competent to practice surgery on account of lack of training, they feel very indignant and they say: "Why, you had to learn. You killed a lot of patients learning this."

What can we say? Those of us who have worked along new lines in the last fifteen or twenty years, who have, so to say, helped to make especially abdominal surgery. We in our ignorance made many a mistake, operating upon many a patient we would not have operated upon to-day; we have had many a patient who died who would not have died to-day, simply because we had to learn and had to do this. The thoughts of this often keep us awake at night.

Because we were obliged to do this in order to open the path for the future, in order to save life, and lessen suffering for coming generations, that does not say that every Tom, Dick and Harry has got to learn this over again, has got to make those same mistakes we have made. We made the mistakes, and we have tried constantly to teach the rising generation of surgeons how

to avoid the mistakes. I do not know of a surgeon in this country who has not constantly tried to show the young man, or the old one, for that matter, who was trying to learn modern surgery, how to do it.

But this takes time, and no one can become a modern surgeon by going to a post-graduate school and seeing a surgeon operate at a distance of 50 or 100 feet. In order to become a modern surgeon he must work directly with the modern surgeon; he must assist him; he must be with him day after day, month after month —yes, year after year, certainly not less than a year. Then he will probably appreciate the difficulties of diagnosis, the difficulty of selecting the right kind of operation, the difficulties of picking out the propitious time and moment for each individual patient. Then he will pick up some of the fine points in the technic, the minutiæ or reason why doing one little thing, or by not doing it, brings success or failure in an operation. Providing also the aspiring surgeon has had the necessary preliminary training.

I once read a paper of what a surgeon should know and it gave all the essentials: That he should be a scholar with a good education, that is to say, he should know Latin, Greek, history and mathematics, and be a good anatomist; know all about signs and symptoms of diseases; know something about chemistry, bacteriology, etc. It was a long story, but the essayist forgot to mention one thing, and that was the principal thing of all. He forgot to say that a surgeon needed a fine Italian hand.

The man who has never done any mechanical work, or who was not raised on a farm, or who was not allowed to make a little sleigh or a baseball bat when he was a boy, or who never worked around in the garden, or played ball or the piano, or who never made pills in a drug store; the man who had never developed a mechanical hand from his earliest childhood, will never be a good surgeon. The man who simply studied all his lifetime and whose father was kind enough to buy him everything from a wagon to a book, who was never taught to draw and to cultivate an artistic eye or develop the sense of symmetry and proportion, that man will never be a surgeon—it is not in the nature of things.

If I read, for instance, in a cheap medical journal, an editorial something like this: "We've quit sending. We do our own surgery, having to provide for our own wife, our own children, ourselves. If we don't know how to do an operation we'll go to the post-graduate schools and learn how, and charge accordingly. If we haven't the skill that comes from experience, we'll get it just as the professor got it, by doing the operation at every opportunity till we become adepts. And who can blame us if we determine to do our own work ourselves? Are we not equally M. D.'s, with equal privileges? This reference of cases to specialists is in many cases unnecessary, anyhow. Very often it is simply because the doctor is too busy to attend to the matter himself. But the real remedy is for him to charge enough to make it worth his while to buy books and apparatus, take special instruction and do the work. Do you have many cases of eye, ear, nose and throat affections? Open your purse-strings. Come to the city and take a post-course; buy the apparatus. It will cost you up to $500, but if you can not make $1,000 a year out of the results you are not much of a business man, and not apt to succeed as a doctor."

It makes me often despair to hear or read such views, but I am consoled with the thought that there are but few members of the profession who would sanction and indorse such ideas.

At the request of many surgeons and physicians from different parts of the state, I emphasize the question of a good surgeon especially, although I object to do it, saying that I can not see the reason why I should always be the objector. But they all insist that I am the very one to do it, as I have passed through all the phases of general practice and surgery, and no one would accuse me of being jealous and envious of the rising rank of surgeons. How much better is an editorial I find in the *International Jour. of Surgery,* which reads as follows:

"We sometimes hear, nowadays, of men who speak of the present rage for rapid operating. Of course, anesthesia has diminished the need for the lightning kind of work and was, in former times, the mark of the good surgeon. The very perfection of our procedures, the care employed in hemostasis, in accurate approximations of divided surfaces, in the application of aseptic dressings that shall also be impermeable to germs coming from surrounding atmosphere, demand an amount of time that would have seemed altogether exaggerated to our ancestors. If there is now a rage for rapid operating, and we can not say that it is very widespread, we must believe that it is a rather favorable indication of progress. Each minute of unnecessary delay increases the possibility of infection, keeps the patient longer under anesthesia, and last, but not least, tends to cultivate in the operator the habit of leisurely, if not idle, operating, that must result unfavorably to his statistics. The most rapid operators we have seen indulge in no unnecessary bustle and hurry. The great secret of their work is that they make no useless movements, that their assistant staffs are thoroughly trained, that every step of an operation is so clear in their minds that each one follows the last with the precision of clockwork. In other words, every operation is studied out and prepared, and every complication that may arise during its performance has been forseen. This sort of work is true, rapid surgery, and if it has become a rage we are only too glad to realize the fact, and to advise all surgeons to cultivate it."

The medical profession is aware how careless the layman is in choosing a physician. They will pick out anybody who has a sign out, who belongs to their church or lodge, who talks most or blows a good deal about himself, without looking up his pedigree, where he graduated, or if he ever graduated, and never inquire about his capacity. If a layman should be careful in selecting his physician, how much more careful should he be in selecting a surgeon. How absurd to let anybody operate who says he can, unless it is known he has had some practice and some experience. The family physician naturally must do some amount of surgery, every doctor has to; but when it comes to special cases, he certainly should not undertake it. Even if he tells the patient that he can do it just as well; that is all nonsense. We all know that he can not, unless he has taken training in a certain direction.

There is not a doctor here that would allow everybody to operate on him for a cataract, or operate on him for appendicitis. There is not a physician here who would let anybody operate on his wife for a papilloma on the vocal cords, nor would any physician present allow anybody to operate on his mother for vaginal hysterectomy, or on his sister for an ovarian tumor. The only fair and honest way is to ask yourself the question, What would you do? Put yourself in his place.

There is another very important point in connection with this, and that is the time to study. A man who is a general practitioner and has to make many calls can not be a good student and keep up with the progress in all branches. Therefore, when a man gradually emerges from general practice to surgery he must devote himself exclusively to the latter. If he attempts to do general practice he will not have time to study; hence, will be a fossil in a short time. In my own experience, where I limit myself exclusively to abdominal surgery, I hardly have time enough to read what is written on this branch of surgery alone and also keep up, to a limited extent, with the general progress of medicine.

Always bear in mind that my remarks refer to special surgery, not simple everyday occurrences, such as fractures and injuries of all kind, and the simpler operations; these the general practitioner must attend to. What I am pleading for are so-called cases of special surgery, which generally are not emergency cases, and where there is plenty of time to select the best surgeon for that particular case. I refer to delicate operations on the eye, the most difficult operations in the throat, and the complicated operations in the abdominal cavity.

Finally, you will ask me: "Who could or should be a surgeon?" In answer I will say that he must be a well-educated physician, must have been a general practitioner and a good therapeutician. He must take up surgery early and gradually develop a surgical hand; he must be an assistant of a first-class surgeon for at least a year, where he will see hundreds of operations of various kinds. Such a man may be a good surgeon. He ought to be in some large town, say a county seat, and, as his surgical practice grows, he ought to give up absolutely general practice and devote himself to surgery exclusively, and then his colleagues in the county would support him. Hence the requirements of modern surgery are:

1. A patient brought to the highest state of resistance to microbic infection and made as clean as possible.
2. An operating-room, preferably in a hospital, where everything has been made thoroughly sterile. This includes anesthetizer, assistants and nurses.
3. A surgeon who has a mechanical hand and has received a long, thorough training.

A REPORT OF FOUR CASES OF FAT NECROSIS IN CONNECTION WITH GALLSTONES.

W. A. EVANS, M.D.

CHICAGO.

The fact that I was able to find fat necrosis in three cases, and to learn of a fourth case in the course of two weeks, all of such cases either coming to autopsy or observed during surgical procedure, would indicate the probability that fat necrosis is not infrequently associated with gallstones, and that there is a necessity for more effort to differentiate gallstones with necrosis from gallstones without it.

So far as our information at the present time would indicate, the only immediate value of such a differentiation would be in the line of prognosis. It is reasonable to conclude that more accurate and extensive observation would eventually lead to betterment of treatment, either in the matter of improved surgical technique, new surgical procedure or improved treatment along medicinal lines.

Many authors have written of gallstones as prominent etiologic factors in fat necrosis, and in lesser measure in pancreatic auto-digestion. The most striking contribution to the literature of the subject is that of Halsted and Opie in the Johns Hopkins Bulletin, for 1901.

The condition is usually unrecognized prior to operation or autopsy. In the case occurring in the service of Dr. Herrick, at Cook County Hospital, the clinical diagnosis was cirrhosis of the liver, and the comparatively localized fat necrosis was found at postmortem examination. In the case of Drs. Roehr and O'Byrne the preoperative diagnosis was gallstones, with suppurative cholecytitis. The diagnosis of complicating fat necrosis was made by the examination of a specimen removed at the operation. It was confirmed by postmortem examination. In the case of Drs. Wells, Lewis and Davis, the diagnosis was gallstones, and the complicating fat necrosis was not suspected until it was revealed by the operative procedure.

In the case of the Drs. Beck the diagnosis was gallstones, but there was quite a general conviction that there was some morbid entity in the abdomen other than stones. Some of the consultants suggested that there was an appendicitis, and others had noted this vague something without being able to assign a reasonable explanation for it.

At the operation, after the gall-bladder had been drained, the foci in the omentum were observed, while a search was being made for the appendix. The appendix was found to be normal. Some of these foci were removed, and sections of them are shown here. This case proceeded to a somewhat uneventful recovery.

It is probable in this case that the presence of fat necrosis as a complication would have been overlooked, both in the diagnosis of the case before operation, and in the diagnosis as made at the time of the operation, had it not been for the fact that it seemed advisable to explore the peritoneal cavity in the direction of the appendix.

The bearing of this point is this: Is it not possible that a moderate amount of fat necrosis is very frequently overlooked, both in the diagnosis made before the operation and in that made at the time of the operation?

HISTORY OF THE CASES.

CASE of Drs. Davis, Lewis and Wells: A woman, 45 years old, had had several attacks of gallstone colic during the last eight years; only one of these was associated with jaundice. The last attack of gallstone colic did not seem to differ from the preceding attacks. After the acute pain had subsided in this case, there remained a great distress. A feeling that it was difficult for the patient to describe; a painful disagreeable sensation in the upper segment of the abdomen, but impossible of accurate localization. After three or four days symptoms of localized peritonitis developed. Five or six days after development of these symptoms the patient was operated. Two hundred and fifty calculi, approximately, were removed from the gall-bladder. The gall ducts were explored, but no stones were found therein. There were found adhesions, comparatively recent, in the upper abdominal segment. The omentum was studded with yellowish-white nodules. These were soft and mealy in consistency. Two were removed for microscopic examination.

The patient seemed to do very well for twenty-four hours subsequent to the operation. Then there came vomiting and fever, and six hours later, or thirty hours after the first operation, a secondary one was done, during the course of which the patient died. Prior to the first operative procedure the pulse ranged from 80 to 100, the temperature was essentially normal, and the only point that attracted the doctor's attention as out of the ordinary was the general feeling of unrest and the demand for relief from a somewhat illy differentiated something.

Case of Drs. Roehr and O'Byrne: E., age between 30 and 40, large, heavy, florid man, six feet, weighing 240 pounds. For three years he has had often recurring attacks of biliary colic, accompanied by occasional jaundice. The general health between attacks is good. He has been ailing with symptoms of gallstones for the last four to six weeks.

Examination, August 10, gall-bladder was dilated, abdomen tense, stools white. Urine contained bile. Jaundice very marked. Temperature 98; pulse 90. Respiration somewhat irregular, irregularity ascribed to severity of spasms of pain.

On the 11th, condition somewhat improved.

August 12. Stools bile-stained. Vomited less. Vomited matter is bile-stained. Temperature 98; pulse 85. Respiration irregular. Abdomen tense and sensitive. Gall-bladder tense.

August 13 and 14. Condition remained much the same. Abdomen somewhat more tense, temperature going to 100. On the 15th, sent to hospital for operation. Some rise of temperature. Evening of the 15th, passed gallstones with stools. On the 16th, operation was done, and the omentum was found somewhat attached around gall-bladder, and also a generally distributed peritonitis around same. Considerable chocolate-colored fluid in the peritoneal cavity.

Postmortem examination made two hours after death, on the morning of August 18. The wound was found nicely agglutinated. There was two inches of subcutaneous fat. There was no necrosis or hemorrhage in this fat. Just external to the peritoneum was a layer of preperitoneal fat, in which there were a large number of foci of necrosis. The omentum was found glued to the anterior abdominal wall, especially in the region of the incision. It is rolled on itself, and reaches to the level of the umbilicus. It is firmly attached to the intestines. It is greatly thickened, and contains an enormous amount of fat necrosis. Some of the nodules are as large as a quarter of a dollar. There is very little fluid in the abdominal cavity. The intestines are distended with gas, especially the cecum. The appendix is a little external to McBurney's point. There is necrosis in the mesenteric fat. The liver does not come to the free border of the ribs, except at the episternal notch. There is some nutmeg, some fat infiltration. Gall-bladder, surrounded by lesions, comes below the border of the ribs; contains some bile, but is not distended. There are a few gallstones in the gall-bladder, but there are none in any of the ducts. There are a few ounces of bloody fluid in the right hypochondrium—walled off. There is some acute nephritis. There is much necrosis in the perirenal fat. There are fibrous adhesions over the surface of the spleen, which otherwise is normal. The pancreas shows fat necrosis, and hemorrhagic pancreatitis.

The lungs and heart are normal. Microscopically, the liver shows fatty infiltration and bile staining. The kidney cloudy swelling, with hemorrhagic exudation. The pancreas shows extensive extravasation of blood, with fragmentation of cells and loss of staining power.

Cook County Hospital Case: Martin J. P., 59 years old; occupation, laborer. Has been sick ten days. Was admitted to the Cook County Hospital on August 14. Service of Dr. Herrick.

History given on the 15th was: Patient has been sick more or less for last five years. Present trouble: About one week ago he noticed his eyes becoming yellow. Abdomen began to swell, and increased for some days. During this time he had diarrhea; urine contained bile. Has not vomited, but has felt like he wanted to. Is continually regurgitating gas into his mouth. Tenderness over liver. Grows weaker every day. Legs have not swollen up. Has had severe fainting spells. During the last five years the patient has had three attacks like the present. Found no blood in his feces. Has had no great pain, chills or fever. He says he has lost 40 pounds in the last five weeks.

Previous History.—Thinks his father died with same disease he has. Has drank whisky excessively for the last three years; drinking as much as 30 glasses a day.

Physical Examination.—Conjunctiva yellowish, slight superficial hemorrhage. Widening of the walls in the lower portion of the chest. Marked prominence of the abdominal walls. Muscles are tense and dulness in the flanks changes by change of position. The liver is palpable, quite firm and quite irregular, extends four or five fingers below the costal arch. Tenderness on pressure.

Spleen not palpable. Area of splenic dulness increased. Patient died at the end of one day at the hospital.

Notes from Postmortem Examination made five days later.—Lividity moderate, jaundice pronounced, abdomen contains a large quantity of bloody serous fluid, omentum full of fat, found rolled above transverse colon, attached in this situation. Petechial hemorrhages in the parietal peritoneum and occasionally in small intestine. Large intestine displaced downward.

Pleura and pericardium are negative.

Spleen 400 gms. 15x4, surface smooth. Parenchymatous nephritis, bile-stained. Liver 2900 gms., very large left lobe, as large as 28x20x10. Capsule thickened. Subcapsular cysts in dome of left lobe; surface irregularly granular, cut surface same. Gall-bladder 16—7 extends two inches below ribs, large quantity of gallstones and débris escapes. Common duct patulous. Pancreas darker than normal. Small shot-like, yellow, soft masses in substance and vicinity. Stomach shows subacute gastritis.

Microscopic examination of the nodules shows them to be fat necrosis surrounded by a zone of hemorrhagic inflammatory reaction.

Histology.—Microscopic sections were made by me of the cases of Dr. Beck, that of Drs. Roehr and O'Byrne and of the Cook County Hospital. The histologic findings in the nodes in each case were the same.

There was a central zone of necrosis; around this was an area of inflammation, productive and exudative as well as markedly hemorrhagic in character. The changes in the central zone were as follows: The action appears a selective one; that is to say, the connective tissue had been partially spared. The primary changes were in the fat. The fat had been so changed that it was no longer soluble in the agents employed in the hardening, clearing, embedding and mounting of specimens. In ordinary specimens made from an area containing fat, microscopic examination will show no fat, other than the quite characteristic area from which the fat has been dissolved. In this specimen the fat was not dissolved, but appeared as a mealy débris which took the hematoxylin stain with a rather diffuse blue. The appearance is similar to that which is given when an area of early calcareous deposit is stained by hematoxylin. The area around this showed a large proportion of blood free in the tissue, considerable numbers of wandered and locally proliferated cells. In none of the specimens was the process old enough to give us an idea as to what would have been the ultimate fate of these areas.

CASE OF DRS. BECK.

Mrs. M. E. had been confined early in May, 1901, giving birth to a healthy child. During the five weeks that followed she was entirely well. On June 20 she developed some pain in the abdomen, but unattended by jaundice or by fever. Between this date and August 3 she had several attacks, in which there was pain in the abdomen. In one or two of these there was a little temperature, and in one or two there was some jaundice. On June 21 she passed a calculus, having the appearance of the half of a split pea. On July 28 she passed another, of somewhat the same size and shape. The attacks in June were less severe than one which came on July 25. In this one there was greater pain, tenderness, greater restlessness, more fever, and more jaundice. A peculiarity of this attack was that on one day there was pain, a sense of resistance, and some edema in the right iliac fossa. On the next day the pain was greatest in the right hypochondriac region, and on the next day the greatest pain and tenderness was located on the left side of the abdomen, not very far from the region of the spleen, and when pressure was made on the right side, the tenderness was referred to this area on the left side. In this attack there were many of the

symptoms that are spoken of as those of shock; projectile vomiting, greater jaundice, greater pain and tenderness, and more fever. For a more detailed report of this case, I refer you to the article of Dr. Beck.

On August 3 the patient was operated on. The operation being such as to drain the gall-bladder and explore the region of the appendix. All over the peritoneum were seen white paper-like dots and lumps. There were some adhesions around the very markedly changed omentum and a hemorrhagic condition of the pancreas.

The gall-bladder was incised and the stones were removed, and some of the white nodules were removed for microscopic examination. No gallstones were found in the common duct. The patient progressed nicely; there was bile in the stools and very little bile drained from the wound. Several days after the operation the bile ducts seemed to have been obstructed and there was colicky pain in the region of the gall-bladder, followed by a large discharge of bile from the fistulous opening.

On one or two occasions while the gall-bladder was being washed, the amount of fluid was a little in excess, and pains of this character appeared and lasted for a few moments. The patient is now entirely well and free from symptoms.

It is to be noted that in each of these cases gallstones were present, and prominent. In none was there a stone in the common duct, or in the pancreatic duct. In Drs. Beck's case a small stone had evidently been fractured, and one fragment was not found at the operation, and some colic arising a few days after operation was supposed to be due to this stone having located in some of the ducts. This complication was transitory.

In the Roehr-O'Byrne case, the stone was passed by the bowel before operative procedure, but the necrosis was already under way.

In Halsted and Opie's case the stone obstructing was found with great difficulty. In each of the postmortems that I made, the stomach, duodenum, pancreas, liver and ducts were all removed together, and the ducts were opened up while yet attached at both ends, so that I am certain that no obstruction existed at the time of death. All of them, with the exception of the Cook County case, had given a history of gallstone colic as a beginning of their attacks.

Let us consider the anatomy of the bile and pancreatic ducts.

ANATOMY OF THE PANCREATIC AND BILIARY DUCTS.

The hepatic duct and the common duct are approximately three times as large as is the cystic duct; besides, it does not have the transverse folds that are to be found in the cystic duct. Therefore, a stone escaping from the cystic usually passes the common duct.

About three-quarters of an inch from the intestinal wall the common bile duct comes in contact with the pancreatic duct. These run side by side through the outer fibrous coat of the duodenum, through the muscular tunic, passing through these coats quite obliquely and running from three-quarters to one and one-half inches through the submucosa. Commonly in the submucosa the two ducts join, making the enlargement called the "diverticulum of Vater." This pierces the muscularis mucosa again obliquely, pierces the mucosa obliquely, in which layer it is somewhat constricted, and empties on the mucous surface from the summit of a small elevation. This is the rule of arrangement, but there is great variation in it. Occasionally it happens that the two ducts open in the intestines by separate openings. There is a fair amount of variation in the distances from the intestinal opening to the point of fusion of the two ducts. It is to be noted that for over two inches the two ducts are either fused, or else in such close contact as that a stone greatly distending the one would obstruct the other to a greater or less extent.

If we allow the possibility that pancreatitis and fat necrosis can follow an obstruction in the duct common to the pancreas and the liver, or even to the common bile duct, after it has reached the muscular wall of the intestine, and remember the frequency of stones in the gall-bladder, we wonder why it is that fat necrosis is not immeasurably more frequent than it is.

For an explanation of this infrequency we have two anatomical facts. The common bile duct is three times as large as is the cystic duct, and the stones having escaped from the cystic duct are expected to pass down the common duct without further obstruction.

The second anatomical consideration is the very great frequency of accessory pancreatic ducts. In a study of 105 anatomical specimens made by Schirmer, some attempt at a second duct was found in all of the cases but two. A separate duct arising from the main pancreatic duct, the duct of Wirsung, and running into the duodenum about one and one-half inches above the orifice of the main duct, was found 56 times. Or, in other words, in this study of 105 cases, a duct capable of draining the pancreas, and at the same time not subject to stoppage by a gallstone, was found in 53 per cent. of the cases.

We conclude that a gallstone may lodge in the bile duct below the point at which the pancreatic duct empties, and in consequence the pancreatic fluid may be dammed back into the pancreas and in addition bile may regurgitate into the pancreatic ducts. The regurgitation of the bile can depend on the variation in the pressure in the pancreas, in the liver and the gall-bladder, and in this regurgitation assistance may be lent by an accessory pancreatic duct. If the liver continues to secrete and bile can not be emptied into the intestine, and if, at the same time, an accessory pancreatic duct was draining the pancreatic secretion into the intestines, it would only be a little while until the flow of bile would be from the bile ducts through the pancreatic ducts into the substance of the pancreas.

On June 9, I made a postmortem on M. D., in the Cook County morgue. This man had died from syphilis of the liver, lung and some other organs. His prominent symptom was persistent vomiting. The stomach and esophagus were bile-stained and the pancreas was bile-stained right to the tail, and there was a tenacious, gelatinous material in the ducts throughout the pancreatic gland. The process was recent, and no necrosis was found either in the pancreas or in the adjacent fat. The only explanation of the bile-staining in the pancreas was the change in the normal distribution of pressure by reason of the change in the direction of muscular peristalsis. Whether necrosis would have ensued in this case I am not in position to say.

Authorities are fairly well agreed that something more is needed for this process than the simple presence of pancreatic fluid. This something is spoken of as lowered vitality, and is ascribed to arteriosclerosis, spasmodic ischemia, etc. Chiari especially holds to this view. The experiments of Flexner, Opie, Fitz, Katz and Winkler are, if carefully studied, confirmatory of this view. In most of their work they tied the pan-

creatic duct with such care as to avoid injury to the pancreas as much as possible, yet the length of time that the experiment lasted—twenty to thirty days—would mean necessarily lowered vitality in the pancreas.

Chiari believes in the existence of two processes: fat necrosis due to a fat-splitting ferment, steapsin, and pancreas and other proteid digestion caused by trypsin. He believes that these processes can exist alone, or either can exist without the other. Flexner's views are, in the main, confirmatory. He adds a third, though superimposed, bacterial infection. Blume suggests that in auto-digestion of the process the sequence is, 1, necrosis of fat islands in the pancreas; 2, leakage of pancreatic secretion into these islands; 3, digestion of the proteids of these areas, and diffusion to new areas.

The distribution of the lesions is somewhat suggestive. Generally speaking, the digestion is limited to the upper abdominal segment. Frequently it extends well over the abdominal cavity. Occasionally it has been found as far away as the bone marrow.

Benda suggests that fat necrosis is frequently present, but is overlooked. He suggests an infiltration method to distinguish such necrotic zones. I did not get results in these cases with that method.

The localization in my cases was as follows: In the case from Cook County Hospital the necrosis was limited to the immediate vicinity of the pancreas.

In the Wells and Beck cases it was probably quite well distributed. In the Roehr-O'Byrne case the necrosis extended beyond the limits of the peritoneum. It was found in the preperitoneal fat of the anterior abdominal wall, though not in the subcutaneous fat directly over it. It was found in great abundance in the perirenal fat. It is probable that the pancreatic fluid finds its way into the peritoneal cavity, and is spread along the surface of the peritoneum. It passes through the stomata of the lymphatics and traverses the membrane, and appears in the neighboring fat. Opie records a case in which the pancreatic duct was tied off for twenty-eight days before the animal was killed. On postmortem, amongst other necroses was found some in the epicardial fat. Flexner reports a case in which the epicardial fat was involved. It is possible that the ferment traversed the diaphragm, went into the mediastinal nodes, and thence regurgitated into the epicardium. It is more probable that the route was directly through the diaphragm into the pericardium. The ferment seems to be easily decomposed, else considerable concentration is required, for there are very few instances in which there is evidence of blood extension, or even of distant transmission by lymph route.

The diagnosis of this condition presents great difficulties. It has been diagnosed before operation once in Chicago that I know of, and perhaps a dozen times throughout the United States. Let us study the symptoms in these cases.

Temperature.—A study of the range of temperature in these four cases would indicate that the temperature would probably give us but little information on the subject. In two of them there was a fever; in two there was none.

It is to be remembered, however, that the diagnosis has to be made from gallstones, and in each of the cases there was enough temperature to indicate that there was something the matter other than gallstones. In the history of the case of Dr. Beck the temperature is given as high.

In the case of Drs. Roehr and O'Byrne the temperature did not exceed 100 until the time of operation. After the operation it went to 102.5 and 103.5 on one or two occasions, but running generally in the neighborhood of 101, and rising in the last hours of life to 107, and probable higher.

If the temperature comes on during the course of gallstones, we must think of suppuration or other like illnesses, as well as fat necrosis. Usually in these cases the pulse was more rapid than the temperature would indicate; for instance, a temperature of 98.5 or 99, and a pulse of 95, and this at a time when no stones were passing, and the pain was not considerable enough to send the pulse up at all.

When I saw the case of Drs. Roehr and O'Byrne, the pulse was a prominent feature, being not only rapid, but running, and accompanied by profound shock. For example, with a temperature of 102, the pulse was 128.

Pain.—In each of the cases the pain, both as to origin and as to quality, would suggest something besides gallstones. It is difficult to describe it in any of the terms ordinarily used in the description of pain, and so the terms, distress, painful sensation, and something wrong, come to be used. There is generally tenderness that is sometimes acute, but is more frequently covered up. As is seen in the case of Dr. Beck, the tenderness may shift, in this case having been on one day in the right iliac region, and the next day in the left.

Fluid.—It is probable that the amount of extravasated blood would never be large enough to furnish any diagnostic clue. In the Cook County Hospital case the abdomen was filled, but the presence of the obstructive biliary cirrhosis would furnish an explanation for that. In the case of Drs. Roehr and O'Byrne, at the operation, fluid was found in the abdomen, but this had disappeared at the time of the postmortem examination, three hours later, with the exception of a small flocculated mass.

Nervous Unrest.—Halsted and Opie have called attention to the difference in the behavior of a patient with fat necrosis complicating gallstones, from that of simple gallstones. The patients are restless, moving about, having a sense of something impending, and ask to be relieved of a something which they do not themselves understand and can not clearly locate; when the patient is simultaneously suffering from gallstone colic, the sharp cutting pains, and the profound shock of the latter condition would completely mask the milder sensations of the first condition.

Lividity.—In only two of these cases did I see the patient. The Cook County Hospital case was seen five days after death, and at that time it was golden-yellow from jaundice and this masked the lividity considerably.

In the case of Drs. Roehr and O'Byrne, the lividity showed some twelve hours before death, as well as at the postmortem. He was breathing quietly in a well ventilated room, with a heart force amply sufficient, and yet the face was markedly livid. I have no observation on the point of Opie and Halsted as a special turgescence in the epigastrium. The epigastrium in this case was covered by a surgical dressing, which may have prevented duskiness from appearing.

In making a diagnosis of fat necrosis there are two conditions that must be borne prominently in mind. Uncomplicated gallstones or gallstones with suppuration of the cyst and acute intestinal obstruction. In differentiating fat necrosis from gallstones, we find the following points: In fat necrosis the pain is generally located in other regions besides that of the gall-bladder. There may be tenderness and pain in the gall-bladder and over

the liver, but in addition thereto there is tenderness in districts somewhat removed. Occasionally this pain and tenderness in fat necrosis is limited and remains in the same vicinity, but more frequently it either shifts about or is never capable of being definitely located. Quite frequently the sensation is not one of pain, but a general uneasiness and a sense of discomfort most prominent in the epigastric region though spreading to other areas. In fat necrosis there is more liable to be temperature than in uncomplicated gallstones, but the temperature is no more prominent than it is in gallstones with pus infection of the gall-bladder. The pulse is usually more rapid in fat necrosis than it is in gallstones, except it be the pulse of shock, which, in a case of gallstones, is not continued for any length of time. In fat necrosis there is a duskiness that we do not get in gallstones. This duskiness, in some cases, approaches a lividity. Halsted and Opie have called attention to a passive congestion or deficient oxidation in the epigastrium in cases of fat necrosis, and this symptom calls for further in-

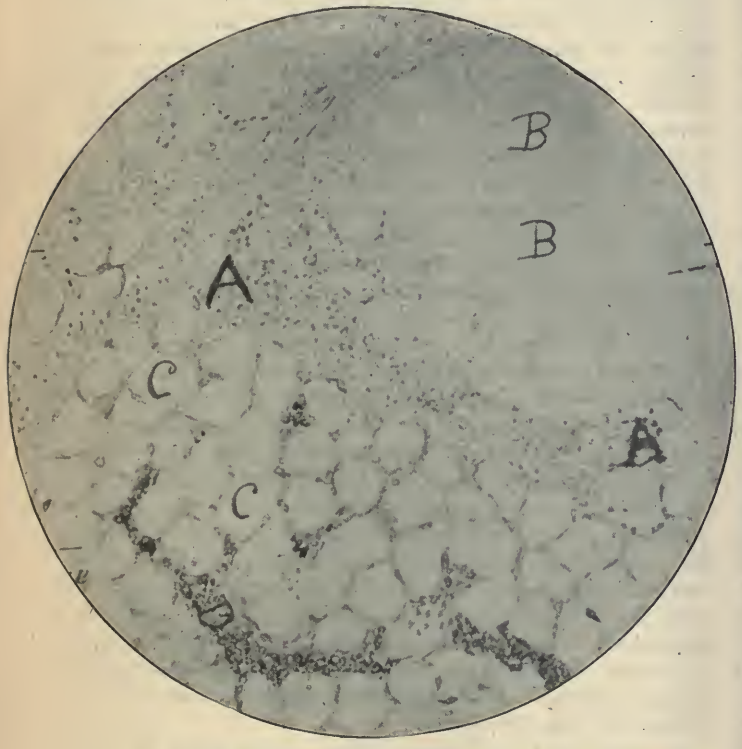

Fig. 1.—Drs. Beck's case. An area of fat necrosis surrounded by an hemorrhagic inflammatory zone.

A. Inflammation. B. Fat necrosis. C. Normal fat. D. Blood.

vestigation, and finally there is in the bearing of the patient, his mental state, the general unrest, an indication that there is something more the matter than gallstones.

We are to bear in mind that very frequently our diagnosis is to be made between fat necrosis and the soreness that remains after an attack of gallstone colic and not between fat necrosis and the acute colicky condition. The persistence of this uneasiness, this pain, this tenderness should be suggestive.

The second condition with which fat necrosis is very frequently confounded, is acute intestinal obstruction. In this diagnosis assistance is lent by the history in the article in *Progressive Medicine,* written by Einhorn; these statements occur: "In most cases (of fat necrosis) described in the literature there was a history of repeated attacks; of a habit of indigestion. The attack which culminates in the disease in question is often one of several not differing in its inception from others already recovered from, except in its severity and persistence. In intestinal obstruction the vomiting is usually more prominent, more persistent and not infrequently is fecal. Occasionally peristalsis can be made out through the abdominal wall. In fat necrosis the vomiting is usually not very prominent, not very persistent and is never fecal. The intestines are quiet rather than otherwise. In each there is liable to be constipation, but the constipation will probably be more marked in intestinal obstruction than in fat necrosis. In each there will be pain, but of an entirely different character. The tenderness of fat necrosis is much more extensive, widespread, less localized than is that of intestinal obstruction. In each there is shock, but shock in fat necrosis does not approximate the shock of intestinal obstruction except the pancreatitis be distinctly of the hemorrhagic variety in which set of cases that feature completely masks the clinical picture. In no one of these cases would intestinal obstruction have been suggested.

FAT NECROSIS FROM A SURGICAL STANDPOINT.

CARL BECK, M.D.

CHICAGO.

The information which we now possess in regard to fat necrosis is principally the result of the study of postmortem findings and extensive experimental work on the lower animals. On the living subject it was discovered but a limited number of times, during operations. The cases usually terminated fatally. Thus far only two cases have been recorded in the literature which recovered from this affection, although a great many cases might have recovered spontaneously without having been discovered.

Having had the good fortune to observe a case which did not terminate fatally, I am prompted to publish my observations, trusting that my remarks will add some to the knowledge of this subject. The history of the case is as follows:

Mrs. M. E., 26 years old, mother of two healthy children, had always been in good health, with the exception of an attack of jaundice six years ago, which followed an ocean trip. The jaundice was very marked, and lasted three weeks, but apparently left no permanent sequelæ. Three weeks after her last confinement, about June 1, 1901, she was attacked with a severe pain in her stomach, which lasted one day, and was relieved by injection of morphin. No jaundice; no temperature. Two weeks later another similar attack followed; pain most severe in the right hypochondriac region, radiating to both shoulders. This time it persisted for nearly thirty-six hours, but gradually disappeared. No jaundice; no temperature.

On June 20 the patient had a severe chill, vomited four times in rapid succession, and had a severe pain in the right hypochondriac region. Morphia gave slight relief. Temperature normal; no jaundice.

June 21, temperature rose to 102.4; pulse, 96.

June 22, temperature, 101; pulse, 90. Pain very much reduced. The patient having had no passage for three days, in spite of cathartics, a high rectal injection, with fair result, was effected, but no stone was discovered in it.

June 23, temperature, 99.4; pulse, 90; bowels moved, but no stone was discovered.

June 24, temperature normal; pulse normal. Another passage was produced, and this time a calculus the size and shape of a split pea was found in it. It was a fragment, however, probably half of the stone, and several facets were distinctly visible on it. From this day on, the patient was apparently well, until a month later, when, on July 25, she

was attacked by a biliary colic. It began at 5 p. m., and before midnight it was so violent that the patient begged for more morphia after three-eighths of a grain had been injected. She had a very restless night, and in the morning for the first time we found the patient slightly jaundiced. Urine contained bile.

Fig. 2.—Case of Drs. Roehr and O'Byrne. A loop of intestine with small nodules of necrosis in the mesentery. Lines show some of the nodules.

Temperature rose to 99.6; pulse, 92.

July 26, the temperature rose to 101.2; pulse, 100; and the patient complained of pain in the entire abdomen, especially, however, in the right inguinal region. At this time the pain in the region of the gall-bladder, however, was lessened, so that palpation was possible.

Fig. 3.—Another Illustration from same case as Fig. 2.

July 27, the pain in the appendix territory seemed to increase. There was rigidity and sensitiveness on pressure. Temperature, 101.5; pulse, 104; jaundice very much marked. Urine dark; stools very light color, but contained no stone.

July 28, tenderness still present; temperature, 100; pulse, 96. On straining the stool, another stone, a half like the first time, was found. It would appear that inasmuch as two halves of a calculus were found, that in all probability these two were the parts of one stone, but on close examination it was evident that they could not have been parts of the same stone, and that each had to have its missing half somewhere in the bowel or gall ducts.

July 29, temperature returned to 99; pulse, 88, and the pain was also very much lessened. Jaundice also diminished.

July 30, temperature and pulse became normal; tenderness disappeared, and while we were commenting on the great change for the better, a sudden and most severe pain in the right hypochondriac region seized the patient, projectile vomiting was accompanied with the same, and after one hour the pain increased to such severity that we had to resort to chloroform anesthesia, three-eighths of a grain of morphia hypodermically having failed to produce any appreciable effect on the patient's suffering. The pain in the entire abdomen increased; there was marked tenderness, but the most sensitive point was on the left side, just below the spleen. By pressing in the region of the appendix, the pain was felt on the opposite side a little higher than the umbilicus.

On August 1, condition was not changed; temperature, 100; pulse, 92; patient vomited three times, and was cyanotic, especially around the nares and chin. In this condition she was transferred to St. Joseph's Hospital, a distance of about one mile, for operation.

There was no doubt that we had to deal with a case of gallstones, for stones were found in the stools; but we were certain that some additional pathological condition existed. The infiltration and paroxysmal pain in the right inguinal region suggested appendicitis one day, but it shifted to the opposite side the next day, leaving its former site comparatively free. How was this to be explained? The uterus and adnexa were normal, so that we excluded the pathologic condition from these sources. How is the surgeon to approach a case of this kind? Had I exposed the gall-bladder first and found gallstones in it, in all probability the fat necrosis would have escaped our notice. Having found one lesion which partially accounts for the symptoms, we are inclined to be satisfied and make no further search.

I decided first to explore the abdomen through a median incision. On opening the peritoneum, I was surprised to find the omentum as well as the peritoneum of the intestines and mesentery studded with areas of white spots, from the size of a pinhead to 5 millimeters in diameter. They were not round, like tubercles, but angular, flat, and somewhat depressed. Their color was white, which reminded one of the sprinkling of lime. At first sight I thought I had to deal with tubercular peritonitis, but a portion of the omentum was excised for microscopic examination, and it proved to be fat necrosis (Fig. 1).

In places where these necrotic areas were numerous were adhesions, and this was especially marked in the left hypogastric region and in the region of the appendix, but the appendix itself was normal. The abdomen was now closed and a separate incision was made over the gall-bladder. On opening the same two barrel-shaped stones, the size of large hazelnuts, and several small stones, among them one fractured half, corresponding to the one passed some days previously, were found. The common duct was examined and found free. The region seemed suffused with blood, so that we thought there was some hemorrhage. The gall-bladder was drained in the usual manner.

The after-treatment consisted in absolute rest to the upper digestive organs. No food or medicine was given by mouth for nine days. The entire feeding was done per rectum, and was tolerated admirably, and kept the patient in a comfortable condition. The daily amount of nourishment was 32 ounces of milk, 6 whites of eggs, and 10 grams of somatose. The draining of the gall-bladder was purposely kept open for a long time to relieve the ducts. The patient made a good recovery.

The observation of one case does not permit one to draw conclusions, but it will teach us something.

It has been remarked that gallstones have some causal connection with fat necrosis; at any rate, it is remarkable that they are so often associated. Therefore, it is advisable to watch for cases of fat necrosis and biliary colic. Certainly, the etiology can not be so simple as the hypothesis of some experimenters would indicate. A gunshot wound of the pancreas has caused extensive fat necrosis within thirty-six hours of the accident.

Clinically, diagnosis is at present almost impossible, if one will not include the possibility with every abdominal lesion. The symptoms are so indistinct that the discovery of it will come as a surprise. I thought I would recognize hereafter every case, but only a week ago I made the diagnosis of intestinal obstruction from a large umbilical hernia in a lady 74 years old. Upon opening the abdomen we found gall-bladder and pancreas necrotic, and abscess and fat necrosis. The patient died twenty-four hours after the operation. She had had no symptoms of gallstones. The shifting pain of the abdomen, the severity of the pain, which is not easily subdued by narcotics, and required chloroform in our case, the lividity or cyanosis, seem to be most suggestive in the diagnosis.

Pathological diagnosis is easy for those who have seen the condition once. The color and the shape of the necrotic areas make their recognition positive. The prognosis, according to the statistics, is very bad, but it may be that some recoveries have been overlooked.

As to the treatment, the principal points are these: We must be positive that there is no obstruction left in the gall ducts before closing the abdomen. If we regard the obstruction of the common duct as the cause of fat necrosis, we must remove the obstruction at once, and not be satisfied with simply draining the gall-bladder, or the fat necrosis will progress and kill the patient. Necrosed portions of fat, as my case proves, are likely to heal, so that in the necrosis itself, if not too extensive, there lies not the greatest danger.

Of the after-treatment of such cases, I regard it as essential to put the entire upper digestive organs to rest for at least a week, or longer, if possible.

Very Early Sign of Stenosis of the Pylorus.—Bouveret calls attention to a sign of stenosis of the pylorus which occurs in the very earliest stages, and may reveal the existence of cancer of the pylorus, while anorexia is slight and before vomiting or tumefaction have appeared. Undulation of the epigastrium is noted in the advanced stages, and is due to a clonic spasm of the gastric wall, while the new sign he describes is a tonic spasm. (*Sem. Méd.*, April 3.) If the patient reclines, the upper portion of the epigastrium is more protuberant on the left side, and is resistant on palpation. The phenomenon appears as if a rubber bulb under the skin were inflated for a few moments and then subsides as the air is expelled. This intermittent tension is never so pronounced as the epigastric undulation, and occurs only during the first few hours after eating. The two signs may blend together during the transitional period.

THE TREATMENT OF TYPHOID FEVER IN CHILDREN.

HENRY E. TULEY, A.B., M.D.

Professor of Obstetrics, Kentucky University Medical Department; Visiting Physician Masonic Widows' and Orphans' Home.

LOUISVILLE, KY.

The writer intends to advance nothing new nor original in the treatment of typhoid fever in infancy, but rather to chronicle those remedies and measures which have, in a somewhat limited experience, proven most valuable in the care of these cases. Some time ago the occurrence of typhoid fever in infancy was denied by many authorities, but numerous cases have been recorded by competent observers in the last few years, in which it has occurred in very young babies and many in children under 10 years of age. Its frequency then in infancy and childhood is generally acknowledged.

In watching the cases of typhoid fever in children coming under the writer's observation, the futility of attempting to care for them without skillful and careful nursing has early been a forcible conclusion. Absolute rest in bed in the recumbent position is the first essential in the treatment of this disease and every one familiar with children knows that this is only obtainable by the closest scrutiny and care. The little patient should be confined in bed and not allowed to be held in the lap, rocked or handled. This frequently is not possible without the assistance of a skilled nurse, to whom must be given the entire charge of the little patient, even to excluding the mother and family from the room if this quiet and rest is not otherwise obtainable. It has been our misfortune to have some spoiled and peevish children under treatment and it has never failed to happen that under the care of a nurse exclusively, the worst would be tractable and obedient. This is difficult of explanation to most mothers but not of demonstration. In such cases the attending physician must be despotic and autocratic, his patient's life depends on it. Where the child is tractable and good, and the mother has other children and other duties, the skilled nurse is more essential, as a child with typhoid needs the undivided attention of one nurse or attendant.

The treatment of this condition in childhood can well be divided, for consideration, into the dietetic, the medicinal, the hydriatic and hygienic. The dietetic treatment is a most important division,—the kind and quantity of food being a difficult problem in many cases. Milk is not suited for every case as an exclusive diet throughout the entire course of the disease; the curds, which form in larger masses than in health may, and most frequently do, act as an irritant to the inflamed area of intestines, doing the same damage that may result from solid food. If milk is the only food which can be given it must be carefully modified, a reduction being made in the percentage of proteids for children even 10 years of age. This can be easily accomplished by any of the many methods of home modification of milk. If the animal broths are given the stools are apt to be more numerous and are always decidedly more offensive than when other diet is given. These broths are not well borne unless, after having been made, they are allowed to cool and the fat is skimmed off before they are reheated and administered. The writer has had excellent results with the administration for a considerable length of time, of some of the many concentrated foods now on the market. The alternation of milk, broth and concentrated food is a

most excellent scheme. To older children butter-milk or kumyss is acceptable, but never will they be taken by young children.

The time of feeding and the quantity to be given are points to be decided only at the bedside of the individual patient. During the active stage of the disease in children, as well as in adults, I have found that but few ask for nourishment, and it is even more necessary to carefully watch the condition of the stomach in the child than the adult. Any undigested food in the action is a danger. If curds appear and milk is the chief article of diet, cut down the quantity, diminish the proteids and lengthen the intervals between feedings. To a child of 5 years, 20 to 30 ounces of milk in twenty-four hours is sufficient and he can get along with much less. Watch carefully the tongue, distension of the bowel, condition of the movements, and regulate by them the kind and quantity of food. Just here it might be well to discuss the importance of a free but proper use of hydriatic measures. The beneficial results from the internal and external use of water are seen more forcibly in children with typhoid than any other condition we have seen. Children take water internally with more freedom and less objection than do adults, and the amount which can be administered should be unstinted; the more the better. However, many patients will not take a sufficient quantity and by a sufficient quantity we mean at least one and a half to two pints in twenty-four hours. The necessary amount can be administered in the form of a saline enema into the sigmoid, the hips being elevated and the anus held to cause its retention. The rectum remains tolerant of this manipulation for many days, even when it is found necessary to repeat these enemas every day.

As to baths, we are firm advocates of their employment throughout the course of a typhoid. It should be put down as one of the axioms in the treatment of this disease that medicinal antipyretics should never be given to control the temperature of a child with typhoid; water is invariably the best antipyretic. It has been impressed upon me, however, that no set rule can be laid down and closely followed as to the frequency of the bath, the temperature for which it is to be given, the temperature of the water, whether a tub or sponge-bath, or its application in the form of a wet-pack. Should the temperature resist a cold immersion bath, a sponge-bath or a wet-pack, it will frequently be found that a cold colonic flushing will bring about the required result. Very frequently we find that warm or tepid sponging or full bath will act much better, with less temporary shock, and control the temperature longer than a cold bath used in any manner. I have on more than one occasion carried a child through a moderately severe attack of typhoid with no internal medication whatever, depending upon hydrotherapeutic measures exclusively.

This brings us to a consideration of the medicinal treatment. No regular routine treatment can be outlined, but one thing is certain, it is not possible to abort typhoid in a child, nor in adults, and the treatment is largely symptomatic. The less medication the better. We have seen but little benefit derived from the so-called antiseptic treatment and the patient is often annoyed by having to take medicine, food, water, etc., at such frequent intervals. Palatable prescriptions are of great importance in treating children and those drugs which are capable of being disguised are best chosen. The mouth should receive careful attention, the teeth being frequently cleansed of the sordes. Oral sepsis may lead to many complications in a child already depressed from the typhotoxins. This may be prevented by the use of mild antiseptics in a menstruum of glycerin acidulated with lemon juice, to which may be added a few drops of myrrh. The mouth should be washed after each feeding, especially when milk has been taken. For the diarrhea which is frequently met, bismuth subnitrate and tannalbin have given satisfactory results in the writer's hands. They are well given with aromatic syrup of rhubarb—6 minims to each teaspoonful. When there is much intestinal distension, and this symptom I have seen occur while intestinal antiseptics were being administered, this condition is best met by the use of turpentine. At best turpentine is difficult to disguise and, when impossible to administer it by the mouth, great good will be derived by the employment of turpentine stupes to the abdomen. These, when renewed frequently and applied as hot as can be borne, will greatly relieve the distension as well as the abdominal pain which may be quite severe. High enemas of normal saline solution, allowed to drain out through the rectal tube *in situ,* give some relief when the gaseous distension is of the lower bowel principally. In the flagging heart so often seen late in the disease, strychnia is the sovereign remedy and it is borne well in large doses by children. It should be given as often as every four hours at least, through the twenty-four. Whisky should be reserved until late and when given it should be with regularity and in a considerable sized dose.

To sum up, then, the treatment of typhoid fever in children: feed carefully; medicate cautiously; nurse vigilantly; bathe frequently; and give plenty of water internally.

The Blood Pressure in the Treatment of La Grippe.—Three diseases are characterized by abnormally high arterial tension—malaria, scarlet fever and cholera, and two by an abnormally low tension—catarrhal icterus and la grippe. The pathognomonic low blood pressure in la grippe seems to be due to the elective action of the infection on the nerves regulating the action of the heart. The symptoms are traceable to the resulting disturbances in the circulation, and improve as the circulation is restored to normal. This can be accomplished by the modern anti-febrile and anti-neuralgic remedies which dilate the peripheral vessels. Federn makes these announcements in the *Wiener Med. Wochenschrift* of June 15, and states that he invariably gives antipyrin or some such remedy in la grippe—both with and without fever—to dilate the peripheral vessels. This reduces their resistance and the heart, weakened by the effect of the infection on its nervous apparatus, is relieved and enabled to restore the circulation approximately to normal. He supervises the blood pressure in chronic heart disease and gives the same remedies for the same reason, watching for indications of atony of the intestines, which he combats with a purgative, fearing that it may enhance the resistance and thus add to the heart's labor. He never gives antipyretics in other febrile affections. He is convinced that high blood pressure is a primary manifestation, the cause or a factor in the production of the arteriosclerosis, and not the reverse, as usually accepted. The excitability of the vasomotor center increases with age, but the blood pressure may be normal even with pronounced arteriosclerosis, while it may be abnormally high with very slight indications of this condition.

Recent Medical Terminology.—Surely it is a work of supercrogation to coin "metopantralgia" when frontal headache is all that it means; and "epicondylalgia" seems to be equally unrequired. "Gastralgokenosis" and stomachache are surely nearly synonymous!—*Brit. Med. Journal.*

THE DIAGNOSIS OF MYOCARDITIS.

In the development of diagnostic skill excellence is judged by the ability of the physician to determine correctly the pathological process or processes. Unfortunately, it often happens that various conditions of disease produce quite similar clinical pictures. To meet this difficulty, medical science was forced to adopt many appellations that acquired great clinical value but failed absolutely to convey any definite ideas of distinct structural alterations or special defects in function. With refinement in methods of diagnosis by the adoption of laborious laboratory investigation, precise physical examination, and detailed anamnesis, greater accuracy has been attained in determining the nature of morbid conditions; names have been introduced that are applicable from both clinical and anatomical standpoints; in short, the designations of the necropsy room have been appropriated by the clinician.

Gradually many familiar and well-worn expressions that served long and faithfully have disappeared and are replaced by more exact terms. But this progress has not ended, nor is it likely that it ever will, and of all subjects those connected with chronic diseases of the myocardium are the best illustrations of this truth.

The hackneyed expressions "cardiac debility," "weak heart," "senile heart," etc., still cover a variety of conditions in the myocardium that bolder clinicians designate collectively as chronic or fibrous myocarditis, but often this diagnosis is not warranted, because there may be no increase in the amount of fibrous tissue in the heart muscle. The symptoms most characteristic of "myocarditis" and those which generally lead the clinician to make this diagnosis, are those of angina pectoris; but when dilatation follows the failure of the heart muscle to compensate for the increased amount of cicatricial tissue in its wall, the agonizing pain, tense anxiety and other features of angina may disappear. Occasional cases of angina pectoris do not show upon postmortem examination either the fibrous myocarditis or the sclerosis of the coronaries that usually precedes it; for such cases the diagnosis of myocarditis would be unwarranted as just stated. In other cases the necropsy reveals a narrowing of the coronaries at their mouths by sclerotic processes in the aorta and perhaps a slight increase of connective tissue that is only discernible with the microscope; for these cases the essential name that the condition deserves should refer rather to the faulty nutrition of the heart muscle than to the increase in fibrous stroma. The symptoms of chronic myocarditis are often simulated by an overgrowth of fat on and about the heart or by degenerative changes in the muscle fibers, or by sundry combinations of these; fatty degeneration or infiltration or both these processes may be associated with fibrous myocarditis.

With these facts before us it is gratifying to observe the broad views adopted by Biggs in his address before the Yale Medical Alumni Association upon "Some of the Clinical Aspects of Disease of the Myocardium."[1] In considering the symptomatology, he admits that there is very little that is characteristic and allows a differentiation of the morbid processes responsible for the cardiac weakness. Among other forms he recognizes an arhythmic type of disease and an asystolic form. The former is often associated with fibrous myocarditis, the latter with disease of the coronaries. Other types are tachycardiac, anginal, asthmatic and bradycardiac. Tachycardia usually accompanies a dilated heart and bradycardia may attend any form of myocardial disease.

If we are to obtain more definite clinical knowledge of the disease of the myocardium thorough co-operation between pathologists and clinicians should be instituted; their combined researches might so correlate the symptomatology of chronic diseases of the myocardium with definite fundamental conditions that in the course of time the various processes now included under "chronic myocarditis" and similar terms may be rendered susceptible of a more definite diagnosis and more intelligent treatment.

DERMOID CYSTS OR EMBRYOMAS OF THE OVARY.

As the outcome of extensive investigations concerning these interesting and important growths, especially by Wilms, it has been shown that teratomas in general and more particularly those of the ovaries and testicle are more or less complicated structures and consist of tissues and rudiments of organs derived from all of the three germinal layers. The arrangement of the tissues and organs is sometimes not unlike that in the fetus. The prominences and protuberances seen upon the cut surface of the cysts contain the various elements referred to, and it is by careful examination by means of serial sections that their complicated structure has been made clear. Not all the tissues of the human body have been demonstrated in these tumors, but careful search is increasing the number of structures found. Thus Katsurada[2] adds to the already large list cardiac muscle. External skin and its appendages; entodermal tubules and cavities corresponding either to the respiratory or to the digestive tract; hyaline cartilage, bone, teeth; glandular tissue such as mucous glands, salivary glands and thyroid gland; parts of the central nervous system, nerves and ganglia; rudimentary eyes and ears have

1. Yale Medical Journal, 1901, viii, 63.
2. Ziegler's Beiträge, 1900, xxx, 179-214.

been found more or less commonly, the ektoderm usually predominating over the entoderm. Often the tissues and parts of organs are arranged as in the human fetus. Rudimentary extremities are not so very uncommon. In one case (ovarian dermoid) Katsurada found the thyroid tissue the seat of marked pathologic changes of a colloid character, and he also found corpora amylacea in the nervous system. It thus seems quite plain that so-called ovarian dermoids really are rudimentary embryos, i. e., embryomas (Wilms).

The cause and genesis are interesting subjects to which much speculation has been given. Any parasitic theory in the ordinary sense is, of course, out of question entirely. Wilms advanced the theory that they arise from the parthenogenetic development of ova, but Bonnet,[1] in a recent critical discussion of this question of parthenogenesis, concludes that in vertebrates, including man, there is in the present state of our knowledge no justification for this hypothesis. Bandler attempted to refer all epithelial formations in ovarian dermoids to misplaced ektodermal cells, but in this way he can not account for the structures of undoubted entodermal origin in dermoids. Testicular tubules have not been found in the vicinity of ovarian embryomas, hence anomalies of that kind can not be made accountable for the growths.

Bonnet suggests the following possibilities: The fecundation by polar globules as observed in invertebrates might lead to further development between the blastomeres of an impregnated egg, and a rudimentary embryo might become included in the inner organs. Furthermore, the experiments of Driesch, Wilson, Morgan and others have shown that small embryos or larvæ may develop from isolated blastomeres of the segmenting egg of various animals. This suggests that embryomas might spring from blastomeres which were dislocated or failed to develop at the proper time and became included in territories in which differentiation had proceeded much further. Bonnet holds that there is no fundamental difference, but merely a relative one, between genuine fetal inclusions and embryomas, and he distinctly favors the idea that the latter may spring from dislocated blastomeres. This does not directly explain the much greater frequency of embryomas in the genital glands, where they may be bilateral and even multiple.

THE IDENTITY OF HUMAN AND BOVINE TUBERCLE BACILLI.

Since Koch's formal announcement of the non-interinoculability of human and bovine tuberculosis the question has naturally been raised whether such non-interinoculability is impregnable evidence of the non-identity of the causative micro-organisms. There is, however, both evidence and analogy that the organisms may, after all, be the same, though differing in pathogenic activity. No fact is better established in bacteriology than the variability in virulence of micro-organisms, which may be increased or diminished by changes in the culture medium, in the temperature to which they are exposed, in their passage through different animals, etc.

There are thus sound reasons for believing that while human tubercle bacilli may be incapable of causing tuberculosis in cattle and bovine tubercle bacilli of causing tuberculosis in human beings, the two micro-organisms may be actually identical, although differing in pathogenic activity; just in the same way as we may accept the identity of smallpox and cowpox, although these are not mutually intertransmissible, while yet reciprocally protective. Some aspects of this most important question are discussed in an interesting and judicial manner by Dr. P. Baumgarten,[1] who cites earlier observations like those recently announced by Koch pointing to the non-transmissibility of human tubercle bacilli to calves and to certain other observations proving the non-transmissibility of bovine bacilli to human beings. On the other hand, it is possible to induce in cattle the classic picture of miliary tuberculosis by means of bovine tubercle bacilli and by modification of the pathogenic activity of tubercle bacilli to induce the anatomic picture of bovine tuberculosis in other animals. Besides, the two morbid processes are identical histologically and in their tendency to caseation and calcification, though perhaps in differing degree.

Finally, bovine tuberculosis exhibits a typical reaction to tuberculin prepared from human tubercle bacilli. It may, therefore, be concluded that the bacilli of human and of bovine tuberculosis are identical, and although the danger of animal infection from human beings and likewise that of human infection from cattle and other lower animals may be slight, it can not be entirely ignored, and the precautions that we have in the past learned to observe should not in the future be relaxed.

THE TREATMENT OF ERYSIPELAS WITH THE SERUM OF ERYSIPELATOUS PATIENTS.

It seems a not unreasonable assumption that the self-limited infectious diseases should be amenable to successful treatment with the antitoxic products of their causative factors. This has been demonstrated on a large scale in the instance of diphtheria, less extensively in that of tetanus and plague, and doubtfully in that of streptococcus infection, pneumonia, typhoid fever and dysentery. Erysipelas is dependent upon a streptococcus, which it is thought is identical with or closely related to the streptococcus pyogenes. Any immunity conferred by an attack of this disease must be brief, as the attack appears to predispose to rather than confer protection against subsequent attacks. It is true that some French observers have reported favorable results in the treatment of erysipelas with antistreptococcic serum, but this experience has not been universal.

1. Berliner Klinische Wochenschrift, Sept. 2, 1901, p. 894; see abstract in THE JOURNAL A. M. A., Oct. 19, 1901, p. 1071.

Believing that the antitoxins of erysipelas are retained for but a short time in the bodies of those suffering from the disease, Valentin Jez[1] was led to employ the serum from such patients in the treatment of the disease. From the median vein he abstracted several grams of blood by means of a syringe, and of the serum obtained after sedimentation in a cool place he injected from 1 to 10 grams in accordance with the severity of the case. The injection was followed within an hour by elevation of temperature, which, however, subsequently declined, until within from twenty-four to thirty-six hours it had become normal. The local condition improved correspondingly. Should improvement not have taken place a larger amount of serum may be injected. In some instances the serum obtained from blisters, induced artificially, was employed in doses of from 5 to 20 grams. As considerable quantities of serum were thus required, an effort was made to increase its potency by oxidation. To this end the serum was mixed with an equal part of hydrogen dioxid and the mixture permitted to stand twelve hours before being used. The results, however, were not so good as followed employment of the native serum; and the same statement is applicable to other modifications that were tried.

The treatment was employed only in ten cases, and it is admitted that this number is too small to base trustworthy conclusions upon. Apart from this fact, the injection into a patient of serum obtained from his own body does not commend itself on general principles, although, as there is no inherent difficulty in or objection to the method, its employment may be sanctioned in order to determine whether it is really capable of effecting the desired result. It is thought that in this way the tissues of the organism are stimulated to increased activity rather than that any antitoxic effect is induced. The number of leucocytes in the blood and the elimination of toxic products in the urine are increased.

"BURKING" UP TO DATE.

Opie Read, in one of the metropolitan "yellow journals," says that a New Orleans "scientist" has recently visited Chicago for the purpose of establishing a suicide resort. This humanitarian from the crescent city of the South is troubled in mind on account of the unpleasant methods adopted by suicides in getting rid of their mortal belongings, and therefore proposes to open a place where death can be had instantaneously and painlessly amid charming surroundings. The only condition is that the would-be suicide shall sign a paper giving his body to the proprietor of the establishment for the benefit of science. Then, seated in a luxurious chair, he will touch a button "and eternity does the rest." There are, according to the statement of this individual as quoted by Mr. Opie Read, twenty-three suicide clubs in the country, and the New Orleans philanthropist has sent his circulars to each, anticipating a liberal patronage. The publication of such an article by a well-known writer is a queer sign of the times. He offers it as a report of facts, without comment, over his own name and with his picture attached, though it has the appearance of a rather rank fabrication. If there were any truth in it, it would be a good subject for an early police investigation and this applies to the alleged suicide clubs mentioned by the alleged "scientist." The publication seems to infer that assisted suicide is a perfectly permissible performance and that there is even a "scientific" utilization of its results. To call it demoralizing is the very mildest kind of criticism.

HAVANA'S HEALTHFULNESS.

The health department of Havana and its suburbs, under the military government of Cuba, is making records. The report for the month of September just received shows a total of 339 deaths, a death rate for the city of only 15.64, a lower figure than New York or Berlin can show for the same period and a very respectable index of healthfulness for any city. The lowest number of deaths for any previous month was 496 in 1899, and the average since 1889, 875.45. Yellow fever, which has averaged 70 deaths each September for the last eleven years and never before had less than 18 victims in the month, this year had only two. Taking the yellow fever year as commencing April 1, there has been an average of 296 deaths each year between that date and the first of October; this year there were only 5. This year, since March 1, the department has had 100 men constantly employed in killing mosquitoes in every known fashion and the above result is, in its way, another experimental proof of their agency in the transmission of the disease. It is not only yellow fever that these measures have prevented; the mortality from malaria has been also reduced nearly 70 per cent. While yellow fever, malarial fever, and to a less extent tuberculosis, are the three diseases most decreased, there has been a general all-around lessening of the mortality, which is attributed to the generally improved hygienic conditions. Smallpox has apparently been wiped out; there have been no cases for over a year. Typhoid caused only seven deaths and diphtheria three. The military health authorities feel more and more confident each month that the solution of the yellow fever problem has been reached, and have little fear nowadays when a focus develops, of its spreading or becoming epidemic. The anxiety will come when the military government is removed and matters are turned over to the Cubans themselves. They have a special responsibility to this country in sanitary matters, and it is to be hoped they will duly appreciate it.

THE SAN FRANCISCO PLAGUE CASES.

There is a curious state of affairs still existing in California. According to the public health reports issued by the Marine-Hospital bureau, and to those of our correspondent, page 1198, there are still occurring cases and deaths of bubonic plague in San Francisco, the last reported on October 10. The reports of the Government commission have been accepted by the world as evidence of its existence there; the State Medical Society also recognized the fact by resolution, and there would seem to be no better established medical fact. The official report of the State Board of Health to Gov-

ernor Gage, recently published in connection with a report of a special health commission appointed by him, declares that the "evil reports of the presence of that disease in San Francisco were based upon error in diagnosis upon the part of incompetent investigators," and that plague does not exist in that city and never has had lodgment there or elsewhere in California. We have here on the authority of the State Board of Health of California that Drs. Flexner, Novy and Barker and the officials of the Marine-Hospital bureau in California, past and present, the former members of the board of health before its reorganization by the Governor, the San Francisco Health Board and the members of the State Medical Society have all been incompetent investigators. This utterance is given out under the authority of the California State Board of Health by W. P. Mathews, secretary. It would have been more satisfactory if the members of the board had individually signed this remarkable report and let the public and the profession know who they all are. They deserve to be immortalized after a fashion as men who in their self-estimation look down upon experts who are recognized as such by all the rest of the world. The members of the special health commission of Governor Gage, to whose report they added their contribution, were not so modest and we find that it consisted of six newspaper men, business managers or managing editors of San Francisco papers, one corporation lawyer and the president of an iron-works. Their qualifications as sanitary experts are not obvious; hence they obtained the backing of the state board for their report. If all this means the discontinuance of state support hereafter to sanitary measures directed against the plague it is unfortunate, but it has that appearance. The determination of the Governor that "one-sided examinations" will not be permitted, however, will be hard to enforce, if he discontinues state aid or co-operation. The United States' authorities will go on in their own way and according to their best judgment, and the medical profession and the country will indorse them.

GALLSTONES AND PANCREATITIS.

The appearance in this issue—pages 1176 and 1180—of two articles on fat necrosis in its relation to gallstones may serve to attract attention to the close associationship between cholelithiasis and inflammatory diseases of the pancreas in the course of which more or less disseminated fat necrosis may arise. The addition to the classical picture of biliary colic of certain peculiar features to which attention is directed by Dr. Beck and by Dr. Evans is certainly a point sure to interest the clinician and to stimulate him to closer study of diseases involving the region of the duodenal end of the pancreas. The intense abdominal pain and the cyanosis, especially of the abdominal walls, which Halsted found among the most striking clinical features in the now classical case, in which acute hemorrhagic pancreatitis and fat necrosis was shown by Opie to be associated with the impaction of a biliary calculus in the diverticulum of Vater,[1] may be regarded as the beginning towards the building up of the complete clinical picture of acute pancreatitis. This is accomplishable only through the careful and painstaking observation and study of the cases presenting symptoms pointing to the cholelithiasis and other lesions in the pancreatico-duodenal region as well as of acute intra-abdominal disturbances in general. In this field the clinician must endeavor to define, at least in its outlines, the clinical picture of the interesting and often widely spread lesions observed after death in such cases as those recorded by Beck and Evans. It is self-evident that the principles of rational treatment may be applied successfully only in the degree that knowledge of causation and ability to correctly diagnose during life advance. Finally, it should not be forgotten that lesions of the pancreas, mostly of an inflammatory nature, are in the end the conditions that determine fat necrosis. It would be a serious mistake to separate the study of the symptomatology and course of fat necrosis from that of the fundamental pancreatic lesion. As far as we know at the present time fat necrosis may be regarded simply as a sign of more or less severe changes in the pancreas toward the relief of which therapeutic efforts should be directed.

1. See Editorial, THE JOURNAL A. M. A., June 22, 1901, p. 1786.

COLD APPLICATIONS IN TETANUS.

The use of cold as a therapeutic measure in tetanus is not new, but it hardly receives a mention in textbooks. Its application in former times has been rather a general than a local one, ice to the spine, for example, from which Carpenter has claimed extraordinary results. Of late years, since we have learned that the disease is in its incipiency a local one, and, therefore, that local measures are important, it has been neglected, notwithstanding the fact that if it can be harmlessly employed in any case it ought to be possible to utilize it as a local remedy. The tetanus germ can not grow or sporulate at even a moderately low temperature, 55 F., and if it develops its toxins apparently at the point of entrance into the system, it would appear that a cooling application below its working temperature would be a rational therapeutic measure. Acting on this presumption Dr. Joseph G. Rogers, a well-known alienist, suggests[1] prompt local injections, deep in and around the wound, of a 20 per cent. carbolic acid solution of glycerin with a 2 per cent. of hydrochloric acid added; and reduction of local temperature of the part by immersions in ice water or ice bags to the part. The first of these measures is based upon well-known intolerance of the germ to these agents, but the latter—the application of cold—is an excellent example of medical reasoning in therapeutics which it is strange has not suggested itself to others. He supports his opinion by reporting two cases, both of pronounced traumatic tetanus to all appearance, spasms involving all the trunk and limbs, which were successfully treated by cold applications to the wounded part. In one case relief was experienced in a few hours and the symptoms ceased entirely on the fifth day of the treatment, when the patient himself removed the ice bladders and a relapse followed. This was again treated as before and in a few days recovery was complete. In neither case were drugs or other local applications employed or apparently required. These cases occurred in the Doctor's practice some years ago, and the treatment was adopted with a view to reducing

1. Indiana Medical Journal, October.

the irritability of the local nerve terminals, and he was at the time satisfied with the theory and practice. In the light of present knowledge he is inclined to ascribe the results to the effect of cold on the microbe, depressing its vitality, preventing sporulation and reducing the evolution and distribution through the blood of the poisons it generated. As a therapeutic suggestion Dr. Rogers' paper, modestly put forth as it is, is worthy of consideration. There is no reason why the treatment should not be tried in every case of traumatic tetanus, not, of course, to the exclusion of other means, but as a possibly valuable and certainly innocuous adjunct.

Medical News.

CALIFORNIA.

Southern California University Medical Department, Los Angeles, held its opening session, October 23.

Los Angeles Infirmary, formerly known as the "Sisters' Hospital," is to be enlarged at an expenditure of from $75,000 to $80,000.

Free Hospital for Consumptives.—After four years of labor, Dr. W. Jarvis Barlow, Los Angeles, has secured subscriptions of $10,500, which will be sufficient to purchase twenty-five acres of land near Los Angeles and to erect at least one cottage for the treatment of poor consumptives.

New German Hospital.—The plans for the new German Hospital, San Francisco, have been passed on by the committee of local architects, and that designed by Kollofrath and Dean has been awarded the first prize. The hospital will consist of a main building and two wings, will be in the medieval style, and will cost $200,000.

Personal.—Dr. Stanley P. Black, Los Angeles, has returned from a six months' course of study in Europe.——Dr. Charles F. Taggart, Los Angeles, the newly appointed chief surgeon of the Salt Lake Railroad, tendered a banquet to the officers of the road, October 15.——Dr. John J. Gallagher, San Francisco, has returned after several years spent in study in the East and in Europe.

GEORGIA.

Examinations.—The State Medical Board met in annual session at Atlanta, October 9, and examined 25 applicants for license to practice medicine.

Scarlet fever is reported to be prevalent in Tallapoosa and throughout Heralson County, and rigid quarantine precautions have been taken to prevent its further spread.

State Sanatorium.—The trustees of the State Sanatorium at Milledgeville met for their annual meeting, October 17. The resignations of Drs. W. A. O'Daniel and Job C. Patterson were accepted. Dr. T. O. Powell was elected superintendent; Dr. James M. Whitaker, first assistant physician, and Drs. Ladrick, M. Jones, John W. Mobley, Middleton L. Perry, N. P. Walker, Augusta, and E. M. Green, Danville, Ky., were elected assistant physicians.

ILLINOIS.

Health Board Enjoined.—The Springfield Board of Health has been enjoined from building an isolation hospital for contagious diseases in Springfield township.

Quincy City Hospital.—The new isolation hospital at Quincy, erected at a cost of $6600, was opened for patients, October 16. In case of emergency, 50 patients could be accommodated in the building.

Personal.——Dr. Mack Jones, Springfield, has moved to Sullivan.——Dr. Farinda J. Shipp, Springfield, is taking a post-graduate course at the Chicago University.——Dr. Francis M. Smiley, Kewanee, is taking post-graduate work in Chicago. ——Dr. Charles Rayburn, Roseville, has located in Kewanee. ——Dr. Samuel A. Graham, Waynesville, has been appointed assistant physician at the Illinois Eastern Hospital for the Insane, Kankakee.——Dr. M. M. Baumgardner, Orangeville, has located in Freeport.——Dr. Charles E. Whiteside, Moline, has returned from Europe.

Barnes Medical College in Good Standing.—In July last, as announced in these columns, Barnes Medical College of St. Louis was declared not in good standing by the Illinois State Board of Health. At the meeting of the Board on October 24 the college was restored to good standing.

Communicable Diseases.—Smallpox is reported at McLeansboro, where 21 cases exist, at Virden 4 cases, at Thayer 3 cases, at Green Ridge 3 cases, Neponset 1 case, Springfield 7 cases, Springfield Junction 10 cases and East Springfield 5 cases.——Diphtheria is reported to be epidemic in Kewanee, where there are more than 100 cases, and at Topeka, where the schools have been closed.——Scarlet fever is reported from Decatur, with 15 cases, from Joliet with 3 new cases, and from Tuscola, where several mild cases have occurred.

Chicago.

Dr. Jesse D. Payne has moved to Blakesburg, Iowa.

Personal.—Dr. Clara Ferguson, for 5 years a physician at the Cook County Asylum and Infirmary, sailed October 26 for a year's study in Vienna.

Dunning Internes Resign.—Four internes at the Cook County Institutions at Dunning have resigned, alleging the following as their reasons: No transfer or rotation of service has been made; attending staff rarely visits the hospitals; the promised laboratory has not been provided; no suitable place to hold autopsies has been provided; attendance at autopsies at other institutions is not permitted; examination of cases at the poorhouse and attendance at operations is not allowed, and because all attempts to get satisfaction have been evaded.

County Hospital Changes.—A new governing body is to be established at Cook County Hospital. An executive cabinet is to be organized, consisting of a physician from each attending staff, a senior interne from each of the different schools of medicine, and the warden. Stricter rules for the assigning of patients in regular numerical order in order that partiality may not be shown to the attending staff will also go into effect. A new rule prohibiting the reception of drunkards afflicted with delirium tremens was passed. Among the powers the committee intends to confer upon the warden is that of removing an interne for cause.

INDIANA.

Dr. Luther M. Irwin, Lafayette, was seriously injured in a runaway accident, October 17.

Scarlet fever has appeared in Jeffersonville, eight cases having been reported during the last week. Clarksville has three cases of the disease.

Vincennes Must Pay.—In the suit of Dr. James N. McCoy against the city of Vincennes for $625, services as smallpox physician during last summer, the jury has found for the plaintiff.

Fined for Illegal Practice.—S. H. Earl, Marion, charged with practicing medicine without a license, was fined $25 and costs, amounting in all to $40.50, on his plea of guilty and agreement to leave the state.

Diphtheria.—The epidemic in New Albany has subsided and it is expected that the public schools will soon be reopened. Three cases of the disease are reported from Princeton. In Stark County, on account of the prevalence of the disease, the health authorities are said to have ordered that all cats in the infected districts be killed.

IOWA.

Des Moines Isolation Hospital.—All differences about the location of the new hospital for contagious diseases have been amicably settled, and the hospital will be erected forthwith at a cost of about $7500.

Iowa Methodist Hospital.—Amended articles of incorporation of the Iowa Methodist Hospital Association have been filed with the Polk County recorder. It was decided to build a new hospital at Des Moines, four stories high, to be constructed of brick, and to accommodate 100 patients.

Personal.—Dr. Tilford L. Putnam, Shenandoah, has been appointed surgeon to the Wabash Railway.——Dr. J. H. Stanton, Harper's Ferry, has gone East to take post-graduate work. ——Dr. Lewis L. Baker, Imogene, is about to locate in Minneapolis, Minn.——Our report of October 19, page 1044, that Dr. Fred. L. Wells, Des Moines, had moved, was unfounded.

KANSAS.

Smallpox.—It is reported that there are 23 cases of smallpox in the Kickapoo Indian reservation in Brown County.

Dr. Alexander Haggart, Ottawa, has been appointed cor-

oner of Franklin County, vice Dr. John G. Van Schoiack, resigned.

Examinations.—On October 1, the State Board of Medical Examination and Registration examined 40 practitioners not graduates of medical colleges and who had not practiced in the state for seven or more years.

Prosecution of the Unregistered.—The days of grace have expired and the State Board of Medical Examination and Registration now announces that it will prosecute all persons not holding certificates from the Board.

Personal.—Dr. H. D. Canfield has returned to Harveyville improved in health and will resume office practice.——Dr. Ludlow, Lindsburg, has gone East to take post-graduate work.——Dr. Ernest W. Minney, assistant physician at the State Insane Hospital, Topeka, has resigned.

Topeka Free Dispensary.—The members of the Kansas Medical College faculty who are interested in the new free dispensary are Dr. Matthew R. Mitchell, diseases of women; Dr. Frank H. Martin, assisted by Drs. Corban E. Judd and O. Portis Davis, surgery; Dr. O. Portis Davis, practice of medicine; Dr. Corban E. Judd, diseases of children, and Dr. Herbert L. Alkire, diseases of the eye, ear, nose and throat.

State Law Evadable.—The State Board of Medical Examination and Registration has discovered that the law under which it was created and under which it operated is defective, and it is doubtful whether the provision prohibiting persons who have not graduated from a reputable medical school from practicing can be enforced. It has been found that quack doctors can evade the provisions of the law which provides that physicians who do not comply with the provisions of the law must cease practicing medicine for pay. In order to convict it will be necessary for the complainant to prove that the physician received pay for his services in the case.

Prevention and Restriction of Smallpox.—In a circular letter, Dr. W. B. Swan, Topeka, secretary of the State Board of Health, says: "Local boards and authorities are strongly advised against the policy of concealment. Smallpox can not be suppressed by denying its existence. It will out more certainly than murder. Official reticence in this is not only useless to protect commercial interests and reputation, but is in the highest degree mischievous, in that it begets false confidence, which may lead the innocent and unwary into such danger as an honest announcement of the facts would have warned them to avoid. Insist upon prompt publicity in every instance."

KENTUCKY.

Typhoid Fever and Diphtheria.—Farmington has an epidemic of typhoid fever from which several deaths have occurred.——About 50 cases of diphtheria are reported from Covington.

No More Smallpox.—Dr. J. N. McCormack, Bowling Green, president of the State Board of Health, reported to the governor that smallpox, which had been so prevalent in the state last winter, had been completely stamped out, so that not a single case remained.

Free Antitoxin.—The health officer of Louisville, Dr. Maverell K. Allen, announces that the Board of Public Safety has arranged for the medical profession to obtain diphtheria antitoxin through the city hospital pharmacist, to be used where the poor are unable to purchase the same.

Sale of McDowell Building.—By order of the Circuit Court at Danville, the historic building on Second Street, known as the McDowell Building, was sold at auction on October 21, in order to effect a division of property interests of the present owners. It was here that Dr. Ephriam McDowell performed the first successful ovariotomy. Efforts have been made in the past by the Central Kentucky Medical Association to purchase the building and alter it as a suitable meeting place for the society, but without success. The growth of the town has left it in an undesirable location.

MARYLAND.

Sanatorium for Consumptives.—At the annual session of the staff of the Endowood Sanatorium for Consumptives, Baltimore, held October 25, Dr. G. Milton Linthicum was elected chairman and Dr. Frank Rich, secretary. Dr. H. Warren Buckler was added to the staff.

Suit Against Sanitary Officer.—Dr. Richard C. Massenburg has instituted suit against R. E. Lee Bosley, sanitary officer of Towson, Baltimore County, for $10,000 damages for alleged slander in stating that the unsanitary condition of his premises in the town is the cause of a case of typhoid fever.

Northeastern Dispensary.—The following have been elected as the staff of the Northeastern Dispensary, Baltimore; Drs. A. D. McConachie, J. Whitridge Williams, S. Rosenheim, S. H. Likes, W. B. Pearce, C. N. Branin, G. C. E. Vogeler, J. C. Beck, Percy E. Lilly, Daniel L. Dunott, T. A. Guier and George E. Starr.

Personal.—Dr. William Osler entertained Professor Wilhelm Waldeyer, of the University of Berlin, October 22. Many of the profession were present.——Dr. Jackson Piper will sail with his family for Europe, November 23, and will spend the winter there.——The Faculty of the Maryland Medical College tendered a reception on October 24 to the ladies who got up the recent bazaar for their hospital. A handsome chair offered to the most popular doctor was awarded to Dr. I William Funk. ——Dr. Robert T. Wilson has been re-elected president of the Hospital Relief Association of Maryland.

MASSACHUSETTS.

Resolutions Regarding Dr. Merchant.—The Hampden Medical Society, at its meeting in Springfield, October 15, passed resolutions of respect to the memory of its late member, Dr. Harry A. Merchant, Monson.

Scarlet Fever and Diphtheria.—Scarlet fever is epidemic in Rochdale, where the public schools have been closed.——At South Hadley Falls, diphtheria is decreasing, but it is feared the failure to observe strict quarantine may result in another increase of the disease.

Personal.—Dr. Hiram H. Burns, Athol, has sold his property to Dr. A. L. Swain, Washington, D. C., and will locate in Plymouth.——Dr. Byron W. McKeen, Cochituate, has moved to Saxonville.——Dr. Thomas J. Cronin, Webster, has disposed of his practice to Dr. Arthur D. Bush, Boston, and will study in Vienna.——Dr. Walter N. Sharp, Saxonville, has moved to the west.——Dr. D. B. Sullivan has opened an office in Bondsville.

MICHIGAN.

Diphtheria is reported to be epidemic in Belleville and in Ionia and Iosco Counties.

The Physicians' Mutual Aid and Protective Association has been organized at Muskegon. The object of the association is to prevent imposition on physicians and to enforce payment of bills.

Bacteriologic Building.—A building is to be constructed at the State Agricultural College, Lansing, to be used exclusively for bacteriologic and research work, the cost to be $50,000, exclusive of equipment.

Conference of Health Officers.—The fifth general conference of the health officers of Michigan will be held at Ann Arbor, November 21 and 22. Secretary Baker, of the State Board of Health, has issued a circular urging the common councils of cities and villages to see that they are represented at the meeting. Representatives of the army and navy medical departments will be present.

MINNESOTA.

Diphtheria.—An excess of diphtheria is reported from St. Paul, and the disease has invaded Roseau County.

Personal.—Dr. Mathias H. Cremer and family, Mazeppa, have returned from a three months' visit to Sparta, Wis.——Dr. Hacking, Wood Lake, has moved to Granite Falls.

For Aged and Consumptives.—An infirmary for the use of tuberculous patients and the aged and infirm will be located at the Workhouse grounds, Minneapolis. The plans call for two buildings to cost not more than $20,000.

Smallpox is reported at Brownton, at Pelican Rapids, where the schools have been closed, and at Spring Valley. The fortnightly report of the State Board of Health shows an increase of more than 100 per cent. in the new cases reported as compared with the previous report. A total of 134 cases were reported, embracing 34 localities in 26 counties.

MONTANA.

St. Luke's Hospital, Livingston, has been incorporated by the Bishop of Montana, Drs. Robert D. Alton, William F. Cogawell, and Byron L. Pampel, and others.

Practitioner Arrested.—One of the pioneer physicians of the state was arrested, October 10, at Butte, charged with "maliciously and knowingly carrying on a business or profes-

sion without first having obtained a license from the county treasurer so to do."

Licenses were granted by the State Board of Medical Examiners to 17 out of 27 applicants who were examined, October 2. One woman passed the examination. Two Chinese applicants appeared, but were not granted licenses. One applicant was refused license because he used notes during the examination.

Personal.—Dr. Edgar A. Brooke, Dillon, has moved to Missoula.——Dr. Joseph Weyerhorst, Butte, has been found guilty of practicing without a license from the county treasurer and fined one dollar and costs.——Dr. R. O. Blades, Pipestone Springs, has returned to Hot Springs, Ark.——A physician of Butte was arrested, October 10, for neglecting to report a case of diphtheria.——Dr. G. Leo Hagen Burger, Helena, has returned from the East and has resumed practice.

NEW YORK.

Personal.—Dr. Arthur M. Whaley, Buffalo, has moved to Sault Ste. Marie, Mich.——Dr. H. I. Van Hoeson, Truxton, has given up practice and moved to Tully.——Dr. Willis C. Cook, Brockport, has sold his home and practice to Dr. Lindsey, of Little Falls.——Dr. Charles W. Southworth, Forestville, has sold his stock, practice and goodwill to Dr. Gleeten, Silver Creek.——Dr. Wilhelm H. Keller, Spring Valley, has opened an office in Haverstraw.

Conference of Sanitary Officers.—A hundred sanitary officers of the state met in the Assembly Chamber, Albany, October 24, and began holding a conference regarding sanitary problems. Dr. Daniel Lewis, State Health Commissioner, acted as chairman. Robert C. Taylor made an address on the powers and limitations of local health boards under the public health law. Dr. Herman M. Biggs, New York, read a paper on the attitude of health officers toward tuberculosis in the smaller cities and towns.

Transfer of Insane Patients.—The State Commission in Lunacy has begun the work of transferring the insane patients from the Blackwell Island Insane Hospital to the colony connected with the Manhattan State Hospital at Central Islip, L. I. Accommodations are to be provided within the next few months for 2500 patients. Relief will also be granted to the other New York city asylums, and in addition the commission will transfer New York patients now in the Poughkeepsie and Buffalo State hospitals to the new colony buildings.

New York City.

St. Luke's Hospital, during the fiscal year just ended, treated 2918 patients, gave 90,695 days' treatment and accumulated a deficit of $50,629 51.

Jewish Hospital.—The State Board of Charities has voted to approve the incorporation of the Jewish Hospital which was organized in Brooklyn, October 15.

Hospitals Crowded.—The up-town hospitals are taxed to their limit so that they are daily turning away patients for lack of room and transferring patients by hundreds to the less congested hospitals down town.

Personal.—Dr. Rupert Folger, Whitestone, Borough of Queens, was seriously injured in a runaway accident, October 17.——Dr. William E. Young has been appointed examining physician for the Outdoor Poor Department of Bellevue Hospital, vice Dr. Horace Bigelow, deceased.

City Consumptive Hospital.—The buildings on Blackwells' Island now used in connection with the Manhattan State Hospital, in which are quartered 850 insane patients, will soon be turned over to New York City by the State Commission in Lunacy. It is understood that the city authorities contemplate using these buildings for a city consumptive hospital. The State Board of Health believes that this will be a move in the right direction, as the proportion of deaths from consumption in New York City is greater than in any other part of the state.

NORTH DAKOTA.

The new hospital at Oakes is finished and already has several patients.

Admitted to Practice.—The State Board of Medical Examiners admitted to practice, October 15, ten out of the fifteen who took the examination October 1.

Personal.—Dr. Henry H. Healy, president of the State Board of Health, has decided to move from Michigan City to Fargo.——Dr. George R. Moore, house surgeon of St. John's Hospital, Fargo, has located in Montgomery, Minn.

Fargo Isolation Hospital.—The detention hospital which is being erected near Cass County Hospital is approaching completion so that the city and county will be in position to care for cases which may need to be placed there. There will be accommodation for about thirty patients.

OHIO.

Medical Research.—The directors of the Rockefeller Institute for Medical Research at a meeting held in New York, October 12, appropriated $500 for research to be carried on in the pathological laboratory of Western Reserve Medical College, Cleveland, under the direction of Dr. William T. Howard, Jr., professor of pathology. The research will be prosecuted by Dr. Roger G. Perkins.

Abolishes Pay Wards.—The City Hospital Board of Trustees, Cincinnati, Monday evening decided to abolish the pay ward of the institution, as its maintenance was found to be unconstitutional and proved an extra expense. The number of internes was increased from twelve to thirteen. Dr. John E. Griewe, clinical director, and Dr. David I. Wolfstein, neuropathologist, were given authority to establish post-graduate classes in pathology and bacteriology in the new hospital laboratory.

Illegal Practice.—W. H. Wagner, a herb vendor, of Portsmouth, has been arrested on the charge of practice of medicine without license.——"Dr." Adah S. Horman, Cincinnati, charged with misuse of the mails with intent to defraud, has been sentenced to 18 months' imprisonment in the State Penitentiary and to pay a fine of $500 and costs. The indictment of Dr. Roberts Erskine, Youngstown, for practicing medicine without license has been quashed on the ground that the indictment did not contain the name of the prosecuting witness.

PENNSYLVANIA.

Personal.—Dr. Thomas W. Moran, Stahlstown, has located in Latrobe.——Dr. John W. Denison, Parsons, has gone to Hazleton to take charge of the isolation hospital.

Kensington Hospital for Women, Philadelphia, during the fiscal year just closed, cared for 834 patients, gave 10,514 days of treatment, and 601 operations were performed.

Gift to Hospital.—An operating pavilion, erected at a cost of $16,000, has been presented to St. Luke's Hospital, South Bethlehem, by Samuel Thomas, of Catasauqua, in memory of his wife.

Contagious Diseases.—Diphtheria is ravaging Forrestville and the public schools have been closed. A case has been reported in Charleroi. It is reported as epidemic in Pinerton, Sherett and Adrian, near Red Bank, and at Helm school near Montgomeryville.——Scarlet fever is reported to be epidemic in Erie, Bedminster and Washington, where a public school has been closed.——Measles has caused the public school at Passer to be closed.

TEXAS.

The University of Texas Medical Department, Galveston, held its eleventh annual opening exercises, October 1. The attendance is about 50 per cent. greater than last year.

The University of Dallas Medical Department, Dallas, held its opening exercises, October 1. President, Dr. Samuel H. Stout; Dr. Charles M. Rosser, dean of the faculty; Dr. Thomas D. Wooten, Austin, and President Oscar H. Cooper, of Baylor University, addressed the assembly, and a reception followed.

Smallpox is reported from Austin. At least 20 cases have been reported and quarantine is not strictly enforced.——Work has again been resumed on the All Saints' Charity Hospital building at Fort Worth.——The New Protestant Sanitarium at Fort Worth will soon be opened for the reception of patients. The finishing touches are now being placed on it.

Personal.—Dr. W. F. Blount, state quarantine and health officer, has resigned his position on account of failing health, and has moved to his former home at Flatonia.——Dr. George R. Tabor, of Bryan, has been appointed his successor, and will take charge of the office at once.——Dr. Isaac J. Jones, Austin, has retired from the position of assistant state health officer. ——Dr. Robert H. Harrison, Sr., Columbus, was the recipient of a most beautiful gold-headed ebony cane, October 21, the gift of the East Texas Surgical Society, as a token of its appreciation of his services in behalf of the medical sciences at large.

UTAH.

Dr. Theodore B. Beatty, Salt Lake City, has returned from a five weeks' trip to the Puget Sound country.

Certificates of practice were given by the State Board of Medical Examiners, October 8, to seven applicants.

Salt Lake City's Morbidity.—There were 31 cases of typhoid fever in Salt Lake City, October 13, an increase of 15 during the week; 37 cases of scarlet fever; 6 of diphtheria and 3 of smallpox.

Revocation of License.—The members of the Salt Lake Medical Society have asked the State Board of Medical Examiners to revoke the license of Dr. Edward S. Payne, charged on two counts with performing criminal abortion.

Another Medical College Proposed.—Drs. Harry N. Mayo, Emerson F. Root, Rufus L. McElroy and others held a meeting in Salt Lake City, October 22, to consider the establishment of a medical school in that city. It is proposed to open the school next September.

VIRGINIA.

University College of Medicine, Richmond, opened, October 1, with more than 200 students.

The Medical College of Virginia, Richmond, opened with an attendance of about 150, October 1. Dr. Christopher Tompkins delivered the opening address.

Raise the Standard.—The faculty of the University College of Medicine, Richmond, has passed a regulation providing that in the future this institution will not give credit of one year in the medical course, simply because a student has received an academic degree.

Personal.—Dr. J. Garnet Nelson, Alexandria, has located in Richmond and will be associated with Dr. Charles V. Carrington.——Dr. William R. Jones has returned to Richmond after two months at Rockbridge Alum Springs.——Dr. A. M. Fauntleroy, Staunton, has passed the Naval Medical Board examination in New York.——Dr. Charles L. Siegel, Richmond, has gone to Colorado for his health.——Dr. F. E. Walker has located in Pamplin City.

WASHINGTON.

Quacks Fined.—The "Quaker Doctors" itinerant medicine vendors, were recently fined $120 and costs in North Yakima for violation of the state pharmacy law.

Smallpox, Diphtheria and Scarlet Fever.—Smallpox, in a mild form thus far, is prevalent at Mud Bay; diphtheria is reported in Ravenna Park, a suburb of Seattle, and scarlet fever in Seattle.

Examination.—The State Board of Medical Examiners will hold its next meeting in Tacoma, January 7, 1902, at which time those desiring a license to practice medicine in the state of Washington will have an opportunity to take the examination, which it is necessary to pass before they can practice.

New Hospitals.—The addition to the Everett Hospital, two stories high and with sixteen rooms, will be ready for occupancy early in December.——Sick quarters at the Puget Sound Navy Yard are to be erected at a cost of $6900.——It is rumored that a hospital will be erected in Tacoma for the Northern Pacific Mutual Benefit Association.

Personal.—Dr. Isaac M. Harrison, Seattle, has qualified as a member of the local board of health.——Dr. C. E. Martin, Linden, has moved to South Bend.——Dr. Elmer E. Heg, Seattle, has resigned his position as member of the Board of Health, on the ground that his residence in the city was not sufficient to render him eligible.——Lieut. Frank B. Morse, assistant surgeon, U. S. Army, has been ordered to Fort Walla Walla from the Presidio of San Francisco.

WISCONSIN.

Diphtheria and Scarlet Fever.—The epidemic of diphtheria in Peshtigo is subsiding, but the schools are still closed.——Scarlet fever has caused the closure of the schools of Pleasant Prairie.

Illegal Practice.—Fred L. Mehrtens, "magnetic healer," of Ripon, was convicted of practicing medicine without a license and fined $25 and costs, with the alternative of thirty days' imprisonment.

Fewer Applicants.—The State Board of Medical Examiners found only 22 applicants awaiting it at Oshkosh. The decrease in numbers is due, it is thought, to the rigidity of the examination.

Smallpox.—The epidemic on the Bad River Reservation at Odanah, is increasing. Of the 120 original patients nearly all have recovered, but on October 23 the disease appeared among the adults in virulent form, 15 cases being reported.——At Little Suamico, Spruce and Wequoick, cases have also been reported.

Personal.—Dr. Charles F. Lehukering, Shullsburg, has associated himself with Dr. Charles H. Russell, Darlington.——Dr. G. A. Larson, Westby, has moved to Cashton, where he will be associated with Dr. Cornelius H. Cremer.——Dr. George H. Bacon, Reeseville, is taking charge of the practice of Dr. Robert E. Calhoun, Chesterville, Ill.

GENERAL.

New Electro-Therapeutic Journal.—The *Electro-Therapeutics*, a journal devoted to medical electricity and radiography, has been announced by its publishers, A. L. Chatterton & Co., New York City. Dr. William Benham Snow is to be the editor.

Operation on President McKinley.—The *Gazette Méd. de Paris* concludes an editorial on this subject with the words: "Great praise is due to the American surgeons who accomplished their intervention with the greatest sang-froid and the greatest rapidity. They did their entire duty. Extramedical influences are probably responsible for the optimistic bulletins issued at first."

The Women's Hospital at Manila, P. I.—This hospital is now open and ready to receive patients. It is temporarily located in a 20-room house. The building has been almost reconstructed, painted and thoroughly fitted up as a modern hospital. This was made possible by a series of donations which Mrs. Whitelaw Reid started with $5000. The operating room has been arranged and furnished with modern devices.

Physicians Honored by Yale.—The University of Yale conferred, at its recent bicentennial celebration, the honorary degree of LL.D. upon Dr. John Shaw Billings, director of the New York Public Library; Dr. David White Finlay, professor of the practice of medicine in Aberdeen University; Dr. William Osler, of Johns Hopkins University; Dr. Ira Remsen, president of Johns Hopkins University, and Dr. Wilhelm Waldeyer, professor of anatomy in the University of Berlin.

Alvarenga Prize.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Senor Alvarenga, and amounting to about $180, will be made on July 14, 1902, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in Medicine, but cannot have been published, and must be received by the Secretary of the College on or before May 1, 1902.

Resolutions on Pathophorous Money.—The Minnesota State Board of Health has adopted the following among other resolutions relating to smallpox: Resolved, That all employers of laborers withhold from such employes who may become infected with a contagious disease, and to whom a salary is due at the time of such infection, all monies or wages due him until his discharge from the hospital or place of detention; that monies or wages be withheld from any such employes with suspicious symptoms until the diagnosis of the disease has been determined by a competent physician.

Manila Physicians Organize.—The following announcement was issued by the Manila Board of Health, September 11: "At the request of a number of medical men of this city, the Board of Health cordially invites all registered physicians of Manila and vicinity, including medical officers of the Army, Navy and Marine-Hospital Service, to attend a meeting to be held in the Sessions Hall, Ayuntamiento, at 8:30 p.m., Saturday evening, September 14, for the purpose of organizing a medical society. The co-operation and presence of physicians of all nationalities are earnestly desired."

The Craig Colony Prize for Original Research in Epilepsy.—Dr. Frederick Peterson, 4 West Fiftieth Street, New York City, offers a prize of $200 for the best original unpublished contribution to the pathology and treatment of epilepsy. Originality is the main condition. All manuscript should be submitted in English. The prize is open to universal competition. Each essay must be accompanied by a sealed envelope, containing the name and address of the author and bearing upon the outside a motto or device, which is to be inscribed also upon the essay. All papers received will be submitted to a committee, consisting of three members of the New York Neurological Society, and the award will be made upon its recommendation at the annual meeting of the Board of Managers of the Craig Colony, October 14, 1902.

Health of Army Good.—Surgeon-General Sternberg, in his annual report to the Secretary of War, says that the health of the army has been unusually good during the calendar year 1900. The admission rate to hospitals from all causes, volunteers and regulars, with a mean strength of 100,389 in 1900, was 2,311.8 per thousand of strength as compared with 2,178.1 in the previous year. In the Philippine Islands, with a mean strength of 66,882, the admission rate was 2,621.96, as compared with 2,395.52 in the previous year, this increase being mainly due to disease among the volunteers, the ratio for which rose from 1,859.21 to 2,761.79. The death rate in China was large, 47.76 per thousand of strength, 23.62 from disease and 24.14 from injury. The health of the troops in Cuba during the year was excellent. As a result of American occupation nearly every city and town has had its sanitary condition improved.

The Association of Physicians Speaking French.—The organization of this new medical association, "des Médecins de langue francaise de l'Amerique du Nord" has met with some opposition, but its success seems now to be assured. The first meeting will be held at Quebec in 1902, in honor of the semi-centennial of the founding of Laval University. French-speaking physicians do not feel at home in congresses and associations where English alone is spoken. They are puzzled by the imperfectly understood language and unable to express their own ideas, the *Bulletin Médical de Quebec* editorially observes. In a homogeneous association, where they can speak in their mother tongue as they learned it in the schools of Canada, in the Canadian colleges and universities where only French is spoken, they will enter into scientific emulation with their English-speaking confrères and be able to present their scientific achievements in a favorable light. The association will welcome members of any nationality or tongue, but the addresses and discussions must be in French. There are more than 2000 French-speaking confrères in North America from whom the Association expects to be recruited.

CANADA.

British Columbia's Insane.—A return received at the Census Department gives the total number of inmates of the Provincial Insane Asylum of British Columbia at 263. Twenty-six of these are Chinese, and three, Japanese.

Trinity University.—As a result of the meeting of the Board of Endowment and Finance last week a special appeal will be made to raise a fund of $500,000. Of this sum $60,000 has already been subscribed by five members of the Corporation.

Personal.—Dr. Law, of Ottawa, has been appointed medical health officer of that city, Dr. Robillard, who has been health officer for twenty years, having resigned.——Dr. J. E. Craik, a graduate of McGill, has been appointed resident physician at the Isolation Hospital, Porter's Island, Ottawa.

Toronto General Hospital Nurses.—The graduating exercises of the Training School were held at the Toronto General Hospital on the evening of October 25, when a very large class was graduated. The first class was sent out from the institution in 1883, and was five in number. Since that time a total of 347 had received diplomas from this training school.

Smallpox in Quebec.—The smallpox epidemic in the Province of Quebec continues to spread, and the disease has invaded several schools and colleges. It is said that the country physicians refuse to recognize the diagnosis of the provincial board of health in many cases, and the people rely on them, and as a consequence the contagion continues to spread. The present outbreak appears to be of a very mild order.

Raising Standards at McGill.—The Faculty of Applied Science at McGill has posted the following notice on the college boards: "It has been decided by the Faculty that the number of marks required for pass-standing in any subject shall be 40 per cent.; for second-class honors, 60 per cent.; for first-class honors, 80 per cent." The medical standing will also be raised in the near future, and there is a likelihood of increasing the term from one of four sessions of nine months each, to one of five sessions of nine months each.

Fellows for Medical Research.—The Faculty of Medicine at McGill has appointed Dr. G. A. Charlton, of Montreal, and Dr. P. G. Wooley, of Johns Hopkins University, research fellows in pathology. They will work under Professor Adami of the Pathologic Department, and their special work will be to discover means to combat the spread of infectious diseases. Dr. Ford, who was some time ago appointed to the Rockefeller Research Scholarship at McGill, and who has been studying at the Pasteur Institute, Paris, will commence his work at McGill in the near future. The alterations and additions in the medical department will soon be completed.

Toronto Western Hospital.—The annual meeting of this institution was held recently, and the reports show very satisfactory progress. The Toronto Western Hospital was organized in 1896, as it was felt that there was a distinct field for hospital work in the western section of the city. In 1899 a fine site was secured on Bathurst Street, a handsome residence with four acres of fine lawns. Since that date the capacity of the hospital has grown from 30 to 90 beds. By special act of the legislature, the institution has been incorporated, and liberal powers and privileges conferred upon it. Particularly has great progress been made in the Training School for Nurses. The election of officers resulted in Dr. A. A. Macdonald being chosen dean; Dr. John Ferguson, secretary; Dr. J. B. Gullen, treasurer; Dr. Geo. H. Carveth, chairman of the management committee, and Dr. J. McCullough, medical superintendent.

FOREIGN.

Kaiser Wilhelm Honors His Surgeon-General.—The German emperor has conferred upon Surgeon-General Koch the rank of Major-General.

Plague at Naples Eradicated.—Out of about fifteen to twenty cases only eight died. The last case was reported October 5. The authorities claim that not a trace now exists in the neighborhood.

Plague at Liverpool.—There were two deaths from bubonic plague at Liverpool during October, according to the local government board. Bacteriological tests made after death confirmed the diagnosis.

The Virchow Celebration.—Fifty delegates from foreign medical and other scientific societies were present at the festivities. The list included Lister, Baccilli, Cornil, Hansen and Podwyssotzky. The Virchow Fund was increased by 50,000 marks from general contributions, with an additional 100,000 marks from the City of Berlin, thus swelling the fund by nearly $37,500. The Berlin Medical Society announced its intention to erect a building for scientific reunions to be known as the Virchow-Haus. It presented a souvenir volume of its transaction since its foundation, which showed that Virchow had presented communications or engaged in discussions 587 times, besides serving as president for twenty years. The new public hospital now being constructed in Berlin is to be formally dedicated as the "Rudolf Virchow Krankenhaus." Our French exchanges refer with pride to the similar apotheosis of Pasteur nine years ago, and observe that Virchow's familiarity with several other languages besides his mother tongue renders him at home wherever he goes and has undoubtedly been an important factor in his international reputation.

LONDON LETTER.

The Smallpox Outbreak.

The number of cases of smallpox now under treatment has fallen to 169, but fresh cases occur every day. As many as 10 have been reported in one day, but of late the number has been only about 2. The difficulties of checking the spread of the disease are manifold. Thus in Kent, where it is the custom of a large number of the poorer classes of London to resort yearly for a few weeks' hop picking, the disease has occurred in the temporary huts erected for the workers. The great neglect of vaccination in London, previously referred to in The Journal, is illustrated by the following occurrence: A girl, aged 12, the daughter of a coal-porter, came home from school ill with headache. On the fourth day the mother observed a rash and called in a doctor, but on his arrival the child was dead. The disease proved to be smallpox. Six other children of the family have since been removed to hospital suffering from the disease. None of them were vaccinated.

Army Medical Reform.

A new building has just been opened in connection with the Post-Graduate College of the West London Hospital. Presiding at the inauguration ceremony, Sir William MacCormac referred to the large number of officers serving in South Africa who had attended the College with advantage. Many had written in grateful acknowledgment of the value of the training. He approved of the recommendations of the committee appointed by the Secretary of State, which have been already published in these columns. When the medical history of the war would be written he was confident that the results would bear comparison with those of any other war. Much of the distress was unavoidable both on account of the state of war

and the vast field of operations, the long and difficult transport, and the undermanned medical service. He trusted that the changes promised would draw into the Army Medical Service sufficient young men of good quality and promise. He wished some means would be devised of removing the Army Medical School from Netley and bringing it to London, where there would be the constant stimulus of competition and criticism, and the benefit of the unrivaled teaching and clinical opportunities that London offered. He advocated a scheme similar to that of the Kaiser Wilhelm Institute in Berlin, which would enable a number of officers to be attached for duty and yet able to spare time for special study.

Tuberculosis Commission.

The work of this commission has already begun, with a view to testing the truth of Prof. Koch's theory as to the non-transmission of bovine tuberculosis. Prominent among those who are making experiments is Prof. Boyce, of Liverpool. Most of the members are working in their laboratories. It is supposed that the government will provide a farm for the experiments and that the question will be settled in about a year.

Displaced Strangulated Hernia.

At the Clinical Society Mr. Thomas Bryant described the following remarkable case. A woman, aged 32, had femoral hernia for five years and did not wear a truss. She often used force in reducing the rupture, and did so particularly two days before her illness. Vomiting began and became stercoraceous in three days, and she was in an extreme state of collapse. The abdomen was distended but not tense, and there was no swelling in the right femoral region—the alleged seat of the hernia, although pressure with the finger over the femoral canal elicited pain. An exploratory operation was, however, performed. The crural sheath, which did not seem expanded, was opened. A small piece of tissue, which looked like omentum, was seen. The femoral ring was quite clear. On passing a director it was slightly enlarged upwards and inwards and a piece of pale intestine which had been collapsed and invisible became distended and visible. It passed downwards through a narrow opening at the apex of the femoral sheath, an inch or an inch and a half below the femoral ring. At this point the bowel was strongly held and strangulated. On dividing this ring 4 or 5 inches of highly congested intestine were drawn out of a space situated below and to the inner side of the opening in the femoral sheath and reduced. The operation was completed, but as was expected, the patient died in a few hours. The necropsy showed that the sac had been forced through a rupture of the femoral sheath at its lowest part into the connective tissue of the thigh on the inner side of Scarpa's triangle. The seat of strangulation was at the orifice through which the intestine was forced.

Mr. Bryant had never seen or heard of a femoral hernia being displaced into the fatty connective tissue of the inner side of the thigh with the seat of strangulation an inch and a half below the femoral ring and at the mouth of the opening in the femoral canal. But for the history of an old femoral hernia there was nothing to enable the surgeon to localize the cause. An abdominal operation might have been performed and would have proved useless. The good old practice was here followed of first examining the hernial region, in every case of intestinal obstruction associated with hernia. The cause of the displacement was probably the forcible attempt at reduction by the patient. This is, therefore, an example of the third variety of displaced femoral hernia. The first is the well-recognized reduction *en masse*, in which the hernia is reduced behind the abdominal walls still strangulated. In the second a large femoral hernia by rupture of its sac shows itself as a tumor in the subcutaneous connective tissue above Poupart's ligament. In all varieties misplaced force is probably the cause. The case illustrates the aphorism: "In every variety of strangulated hernia forcible taxis is the cause of all displacements of inguinal or femoral varieties, as well as rupture of the sac or sac's contents; so forcible taxis should be avoided."

Treatment of Ascites in Hepatic Cirrhosis by Suture of Omentum to Abdominal Wall.

Mr. Mansell Moullin read notes of five cases in which he had performed this operation with a view to establishing a collateral circulation by the Drummond-Morison method. Two patients died, one four weeks after the operation, from pleurisy, the other one week after from exhaustion. In both, the operation had been performed too late. The disease was too far advanced and there was no time for the development of a collateral circulation. The three other patients were discharged relieved. One could not be traced. The other two were alive and at work at the present time, two years after the operation. As far as ascites is mechanical the operation relieves. The mortality had been high, but with better selection of cases there is no reason why it should be higher than that of exploratory laparotomy. A median incision above the umbilicus is the most convenient. Through it the whole upper surface of the liver can be reached and the omentum fixed to the abdominal wall by sutures passed from its peritoneal surface. Drainage is unnecessary and increases the risk of sepsis. If the fluid collects again it may have to be drawn off—many times in a few months—until the anastomotic channels have sufficiently enlarged.

Hemorrhagic Myositis in Typhoid Fever.

At the Pathological Society, Dr. F. W. Andrews described a case of this rare complication. A young man who suffered from double chronic otorrhea died in a relapse on the fifty-second day, of typhoid fever. A day or two before death he complained of pain when turned over. A swelling was discovered in the left thigh and diagnosed as hemorrhagic. At the necropsy the vastus externus muscle was found to be the seat of hemorrhage. Many fibers showed Zenker's degeneration and large numbers of streptococci pyogenes. The infection was thought to be the cause of the hemorrhage.

PARIS LETTER.

Obstetrical Congress at Nantes. Protection of Infants.

At the Congress of Gynecology, Obstetrics and Pediatrics, held last month at Nantes, several interesting reports were made. One of the latter, by Dr. Olivier and Schmitt of Nantes, was on the protection of children. This protection should begin as soon as possible, Dr. Olivier stating that every pregnant woman should have complete rest six weeks before and six weeks after delivery. An indemnity, equal to two-thirds of the woman's salary, should be given her during that period. There is already a law in France, called the Roussel law, which provides for the medical supervision of all infants who are not under the immediate care of their parents.

The essayist declared that it would be well if infants during the first year could be examined and reported on medically every month during the winter season and every fifteen days during the summer. Professor Pinard, the well-known accoucheur, spoke of the desirability of teaching children something of the importance of taking care of their health. They should be made to understand that their own health will have a direct influence upon that of the succeeding generation. Professor Pinard considered that three months were none too long a rest for women before parturition. Premature birth sometimes took place during the seventh and eighth month. He said also that he did not favor "crèches," where children are placed by mothers, who are obliged to work, because he thought it unwise to encourage this partial abandoning of the child. Professor Pozzi deprecated the tendency shown in schools to force the students to learn too much. He advised the examinations being passed at the end of each year, instead of being placed at the end of the university course. The following resolution was passed by the Congress: "All pregnant women should be placed in the best hygienic conditions during the last three months of pregnancy, and the first month following delivery, and the public authorities are called upon to find the best methods for insuring the realization of this measure of public utility.

Surgical Treatment of Uterine Cancer.

Another important subject, the surgical treatment of uterine cancer, was discussed by Monprofit, Potherat and Segond. A radical cure could only be hoped for from an early operation. Monprofit said he did not believe in very extensive operations. He began by removing the infected tissue through the vagina, tamponed with antiseptic gauze, and then removed the uterus in the same "séance." Pozzi said he agreed with Monprofit, and added that caution was necessary in extensive lesions, as the risk run by patients in such cases was out of proportion with the benefit obtained. Dr. Potherat argued that it was well to cut away from below the cancerous tissue a week before removing the uterus. Dr. Segond considered it was useless waiting so long as the vagina might get reinfected. He did not consider it advisable to perform a radical operation when the lesions were extensive. A simple operation in such cases was often of great benefit to the patient.

Discussion of Alexander's Operation.

Alexander's operation was also discussed. According to Potherat, it would seem to be the best treatment for non-

adherent deviations. Dr. Segond highly praised this operation on account of its simplicity and harmlessness. As a rule, methods which prevent the adhesion of the womb to the abdominal wall or to the adjacent organs, are to be preferred to the others. Professor Pinard made some remarks on the vomiting in pregnancy. It was always due to hepatic insufficiency.

Persistent vomiting is not seen in women who have been treated in a logical manner, and an absolute milk diet is the one and only safeguard. The pulse is the best indication as to the advisability of interrupting gestation. When it is over 100, there is danger, and when it reaches 140, the woman is lost. If after several days of absolute milk diet, the pulse remains over 100, the uterus should be emptied of its contents. Eclampsia was also discussed, Hirigoyen and Schmitt advocating in some cases manual dilatation and removal of the child when labor has set in. Dr. Pinard remarked that statistics published nowadays do not contain a sufficient number of cases, the intensity of the illness varying considerably. He did not believe in active measures, trusting more to chloroform, chloral and milk.

Haycraft's Reaction Studied by Chauffard.

Dr. Chauffard, who has succeeded to Hanot as the best known specialist in France on liver diseases, has been carrying out experiments with the help of F. X. Gouraud to test the usefulness of Haycraft's method in recognizing minute quantities of biliary products in the urine. The urine used should be quite fresh, or at least have been sterilized with a small amount of cyanid of mercury, for instance, 5 to 6 centimeters of a 2 per cent. solution. The urine should be poured into a glass, and a small amount of powdered sulphur deposited very carefully on the surface of the liquid. If there is any trace of bile in the urine, a small amount of sulphur will be precipitated. The test should last, according to Chauffard, about five minutes. This method allows one to detect the presence of biliary salts or bilerubin in a 1 to 50,000 solution, whereas Pettenkofer's test does not go beyond 1 in 1000. Fifty specimens of urine were examined, and a positive result obtained in 20 cases. Salkowski's test and the spectroscope proved the correctness of this reaction.

Bubonic Plague During a Scientific Excursion.

Bubonic plague broke out on the *Senegal*, a steamer which sailed from Marseilles on September 14, with a ship's list of 186 passengers, among whom were about 19 physicians. This steamer had been hired by the *Revue Générale des Sciences*, which had organized a scientific excursion to Asia Minor and Palestine. Two members of the crew were found affected with the plague, and the steamer had to put back to Frioul. All the passengers, with the exception of thirteen, were inoculated. Professor Terrier, Dr. Chauffard and other notable medical men were on board. The plague has since broken out in Naples, and one case of death has already taken place.

Supposed Death from Medulla Cocainization.

A few weeks ago quite a flutter was caused by the political papers publishing the report of a death which would seem to be the outcome of medullar anesthesia. A woman, suffering from a wound of the foot, had been taken to the Beaujon Hospital, subjected to Tuffier's method, and had died shortly after. It was, however, what one calls in French a "canard," showing once more the tendency on the part of the press to incriminate physicians when they can. The surgeon who had operated this patient, Dr. Lyot, wrote to the *Presse Médicale*, and showed by the observation taken of the case that death was due to acute septicemia, which the operation was unable to control. There were no symptoms of poisoning by cocain, and the autopsy revealed no indications of a wound of the spinal cord.

Dr. Crosti, who is surgeon of the Maggiore Hospital at Milan, has been undertaking some operations in Paris in Professor Reclus' service at the Laennec Hospital. Dr. Crosti has remarked that one of the important elements of Bassini's operation is often overlooked. In Bassini's operation a new inguinal canal is established, and to insure a sufficiently strong posterior wall, the fibers of the rectus, transversalis and minor obliquus are sutured to the deep part of Poupart's ligament. These fibers should be well separated from the aponeurosis of the major obliquus and subserous adipose tissue. According to Dr. Crosti silk should be used for these sutures. In some places such as Perouse, Sienna or Rome, some operators use silver wire.

Preparations for 14th International Medical Congress.

The first steps in view of the 14th Medical Congress have already been taken. Professor Julian Calleja-y-Sanchez has been chosen as president. Dr. Angel Fernandez Caro-y-Nouvilas will be secretary and Dr. Jose Gomez-y-Ama, treasurer. The fees for membership will be 30 pesetas. This congress will take place in Madrid April 23 to 30, 1903.

According to the last reports published, there have been no new cases of bubonic plague at Naples, so that the quarantine established against Naples in Rome has been removed.

Marmorek's Serum Spoken of by Bazy.

Marmorek's serum does not seem to acquire much popularity in France. One does not hear of its being used extensively by the urgeons of the hospitals, among house physicians and surgeons, whose opinions reflect and sometimes exaggerate those of their chiefs, it is looked upon with distinct disfavor. Dr. Bazy was speaking about a case which was treated by this serum, and he said he would hardly admit that the cure was due to the latter agent as no proof was given that there was streptococci infection. The observation, he remarked, proved only what can already be called a success, that the Marmorek serum is not always harmful, a statement which has sometimes been made.

Electricity in Treatment of Constipation.

Muco-membranous colitis is a disease which often enough baffles the skill of the physicians who endeavor to cure it by the routine methods of treatment. Dr. Doumer, a Belgian physician, has recently recommended electricity, the continuous current being used as a means of curing the constipation seen in such cases. One patient had suffered from this latter symptom for quite a long period of time, and clinical investigation showed that there was stenosis of the ascending colon. He was subjected to the application of a 10-milliampere current during 10 minutes. The strength of the latter was increased on the following days to 70 and 80 milliamperes, and constipation, as well as all the other morbid symptoms, disappeared completely. Five other patients treated in like manner, gave the same gratifying results. The technique of the author is as follows: Two large tampons of coal, about 6 centimeters in diameter, are covered with chamois skin, dipped in water and placed over each iliac fossa. During the first minute the current is only put up to 30 milliamperes; it is then reversed and increased sometimes to as much as 150 milliamperes. The treatment should be kept up 10 to 12 days. The conclusions of the author are as follows: Such currents are easily and safely administered and can cure long-standing constipation when seen in muco-membranous colitis.

Correspondence.

Tokio as Seen by American Physicians.

Tokio, Japan, Sept. 27, 1901.

To the Editor:—We are in this far away country and suppose a few observations might interest your numerous readers. Tokio, the present capital of Japan, is an interesting combination of the ancient and the modern; its foundations were laid before Columbus discovered America, and it was a great city in the beginning of the 17th century. Its population to-day is about two million. Some of its streets are as broad, as well paved and lighted as the boulevards of Chicago, and others as narrow and dark as in medieval days; tall brick and stone buildings that would do credit to any western capital have thatched roofs of a thousand years ago. The new Japan of to-day is a marvel; our own Commodore Perry held the magic wand that gave her the awakening, and her rapid strides to a higher civilization is the wonder of the age.

Our party had been in Tokio but a very short time when Baron Tomatsuri, commander and surgeon in the royal navy, called, in full regimentals, on Prof. Senn, and announced that he was detailed to attend upon him during his stay, and through him we readily gained admission to all the medical institutions of the city. He went with us through the Imperial University of Tokio, one of the products of the new Japan; it came into existence as at present, in 1886 of our calendar, 2559 of the Japanese; it was formed by the consolidation of several schools, two of which were of great antiquity.

It now consists of colleges of law, medicine, engineering, literature, science and agriculture, with a total of 2700 students.

The College of Medicine has twenty-four chairs, including three in surgery, three in medicine, one each in psychiatry, pathology, gynecology, obstetrics, ophthalmology, pediatrics, dermatology and syphilis, otology, rhinology and laryngology.

Prof. Sato, chief of the surgical department, Prof. Aoyma, of medicine, Prof. Katayamo, of psychiatry, and Prof. Muira, of pathology, were especially courteous in showing us their numerous laboratories, the wards for clinical teaching, the libraries and the excellent facilities generally for teaching. The two surgical amphitheaters surpass anything we have in Chicago for successful asepsis in public teaching. The various wards directly connected with the college contain 520 beds, the Hospital for the Insane has 340 patients, and in easy access to the students there is a hospital for infectious and contagious diseases, and one for chronic invalids. The course extends over four years of 282 days each; there are 350 students in attendance, and the last graduating class numbered 24.

The preliminary requirements are those of the entrance examinations to the University, much the same as the entrance examinations to our own universities. Any general hospital with adequate clinical facilities can conduct a medical college, but the degree and license to practice is given only by a board of examiners appointed by the Imperial government. There are nine medical colleges in Japan.

Main street of the Yoshiwara (Naka-no-cho).

Tokio is the home of the world-famed bacteriologist, Prof. Kitasato, doubtless the greatest living exponent of this important handmaid of medicine: his great work with the bubonic plague and tetanus are well known. He is now earnestly engaged with the leprosy problem, and we have reason to anticipate that he will soon give to the world important revelations that may bring relief in this disease. He conduets a laboratory for post-graduate work, maintained by the government.

I visited with great satisfaction Tokio's model prison, the Sugama, with 1800 prisoners. No country has a prison managed upon higher humanitarian principles. The buildings are all new and of ample size, of brick and stone; the approach is by a long avenue ornamented with trees, flowers and well-kept lawns. The cells are commodious, well ventilated and lighted. There is a daily school and numerous priests of the Shinto faith to give religious instruction. The workshops are numerous and well equipped. All are required to work, and every prisoner leaves there with some trade with which he may earn a support. While in the prison he receives a share in the profits of his labor, varying from seven-tenths to one-tenth, depending upon his diligence, good behavior and the number of times he has been committed, so that he may leave with a reasonable sum of money to begin life anew. Among other articles we found in the workshops were packages of umbrella handles, that were to be shipped to the United States. The trades unions at home have closed the workshops of many of our prisons, yet they carry umbrellas the handles of which are made by convicts in Japan.

Near by this prison there is a reform school for wayward children, conducted by a Japanese gentleman and his wife, Kosuka Tomeoku, who prepared himself for this important work by a prolonged residence at the Concord Reformatory, Massachusetts, and the Elmira Reformatory, New York. These noble people, without government aid, are building up an institution for child-saving that will aid in diminishing the increasing crime in their country as similar efforts have done elsewhere.

In the same locality is the City Hospital for the Insane, the great majority of the inmates being chronic and incurable. The proper care of these is a problem for Japan as it is for us. They are as well taken care of as its crowded condition permits. It is in this respect just like many similar ones in our own country. The institutional care of these unfortunates must be modified; the methods of a half a century ago do not suffice for to-day—Japan is not behind us. This hospital is soon to be replaced by another that I have no doubt will have ample ground, and every facility for occupation and amusement that the patients require, and it will be a comfortable home as well as a hospital.

I was much interested in Japan's method of regulating the "social evil;" it is a question always of deep interest to the physician as the guardian of the health of his clientage. It can not be questioned that so long as many men can not control their passions and some women are frail, prostitution will exist, and the wise sociologist will seek some way to minimize its worst effects.

The work of regulation began here in 1573, in the then capital, the city of Kyoto; the city of Tokio began the same

Courtesans in their "cages."

work in 1617; laws with severe penalties were enacted requiring all courtesans to be licensed and sequestered, and in 1867 the work of medical inspection began. The first place selected in Tokio for the purpose was a marsh overgrown with rushes and it was called Yoshiwara, a Japanese word signifying rush marsh, and this is the name by which all such localities are known throughout the empire. There are six such localities in the capital city to-day, but the principal is the Shiu Yoshiwara, and this we visited. It is almost four miles from the center of the city, surrounded by a moat and a high fence with two gates of entrance and well guarded by the police, and no prostitute is permitted to pass the gates without permission. In this place there are 153 brothels; nowhere in Japan did we find so many expensive buildings for residences and 394 tea houses used largely as places of assignation, with over 3000 courtesans. These women are divided into three classes, according to the price they can command for services. They are under a contract with the brothel keeper, witnessed by the police authorities, for a term of from three to five years, in consideration of a certain sum that has been paid to the parents or guardians, and a further sum for the necessary outfit of clothing and bedding; the prostitute obliges herself to pay one-half her fees for living expenses, and 15 per cent. of the remainder to reimburse the keeper for money advanced. If her income has not been sufficient to discharge her obligations by the time the contract has expired, then she must remain until she has satisfied the keeper in full, which usually means so long as she lives; the practical result seems to be that the

contract is a sale for life. The women of the second and third classes are exhibited after dark in long, narrow cages, where they sit with powdered faces and rouged lips in garments as elegant as possible, waiting to be selected by some one passing by. To the average American this is most intensely revolting; to the average Japanese not at all so. The women of the first class are not so exhibited, but photograph albums are placed at the entrance to facilitate the business.

The medical inspection is as rigid as possible. Without the microscope the record of 1899 shows over 6 per cent. of inmates were infected; those of 1898, 5.5 per cent. In 1898 the number of inspections were 134,607; number of infected cases, 7506; number of guests entertained, 1,237,885. This inspection does doubtless diminish the aggregate of venereal diseases, but no inspection can be, in my opinion, adequate that is not microscopical and does not include the men as well.

The sequestration removes from the streets of Tokio every appearance of social vice, and the man who seeks it must go a long way to find it. The rigid police inspection at the Yoshiwara requires a written description, in considerable detail, of every man entering, and gives excellent espionage of the criminals. One walks the streets of these Japanese cities at night with a sense of security rarely felt in the cities of other countries. This much at least must be said in favor of it, and if the present method of exhibiting the women was stopped its most objectionable feature would be removed.

One of the most pleasing things connected with our Tokio visit was witnessing the marked attention paid our fellow traveler, Prof. N. Senn. On the day of our arrival, Baron Tomatsuri, a surgeon of the navy, with the rank of Commander, was detailed by the surgeon-general of the navy to attend upon him, and faithfully did he do his duty. Morning and afternoon he was on hand to take the Doctor to some new and interesting place, and the whole party is under deep obligations to him for the facilities he afforded for a study of the medical and surgical aspects of the capital city.

A banquet was given Dr. Senn, at which Dr. J. Frank and myself were present. When Baron Tomatsuri invited Dr. Senn to attend the function, I was present; the time fixed for it interfered with our itinerary; Dr. Senn, with that modesty and consideration for the welfare of others—these are two of his striking characteristics—declined, much to Dr. Tomatsuri's discomfiture. I insisted that he must accept and the itinerary must be changed, but considerable argument was necessary to induce him to do it. Dr. Senn wanted an excuse to avoid the publicity.

There were forty physicians present, all assembled in a room in the Imperial Hotel, and on a table in the center of this room were all the books that Dr. Senn has written, except his "Surgery," which has just been published. The menu would have done credit to any Parisian chef. At the top of it, beautifully printed in colors, were entwined the flags of Japan and the United States. The appetites of all having been satisfied by the generous feeding, Baron Haschineato, the Surgeon-General of the Army, acting as toastmaster, arose and proposed the health of each of the guests who were present. On the right of Dr. Senn sat Baron Ishiguro, Surgeon-General of the Army, retired, resplendent with decorations, some of which were won by his achievements in the war between Japan and China. On the left of Dr. Senn sat Prof. Sato, the senior professor of surgery in the University of Tokio. Prof. Kitasato made the first speech. In it he eulogized Prof. Senn for the great work he had done in the advancement of surgery, and emphasized the numerous and valuable contributions he made to the literaure of the profession. Dr. Suzuki, the senior commander of the navy, then arose, talked to the sentiment that the relations between the two countries should be more intimate, spoke of the important factor of Commodore Perry's visits in the beginning of the awakening of Japan, and of the deep obligation they were under to that distinguished American, and of the pleasure it gave them to do honor to another eminent American, and expressed the hope that two countries so close together geographically might be closer together scientifically. Baron Tomatsuri spoke of his pleasant associations with Dr. Senn in Cuba and Porto Rico during the Spanish-and American conflict, whither he had gone to study the surgery of the war, the important work that Dr. Senn had done in military surgery, and of the pleasure he had in his attendance upon him in Tokio.

Dr. Senn replied to these several speeches with more than his usual eloquence, reviewed the wonderful progress of Japan in medicine and surgery, gracefully thanked them for the great honor they had done him, and hoped it might be the beginning of a more intimate medical association between the two great countries.

The function closed in time for us to take a late train to Yokohama, and we were escorted to the train by five of the distinguished physicians, led by Baron Tomatsuri.

Yours very truly, D. R. BROWER, M.D.

Pension Examiners.

MILWAUKEE, Oct. 21, 1901.

To the Editor:—The article appearing in THE JOURNAL under date of October 5, reflecting on pension examiners, is entirely unwarranted, and the department that furnished you with such data is either incompetent or malicious.

It is far more probable that all of these twenty soldiers, aged between 50 and 70 years, should have heart disease than that none of the scarred and rheumatic veterans should have an organic heart lesion. Your comments, you will observe, carries their own refutation. I make small doubt that a far greater percentage of old soldiers have some organic heart lesion than the pension records show. Members of pension boards, through their frequent consultations and large experience, become very proficient in detecting heart murmurs, while many of your "disinterested physicians," I regret to say, can not detect a fairly loud murmur. There is no professional restraint on the pension board; every "suspicious heart" is fully discussed, and you may rest assured that the final dictum of six consulting ears is more trustworthy than the separate finding of a score of your disinterested physicians.

RALPH ELMERGREEN, M.D.

Association News.

Section on Ophthalmology.

To Members of the American Medical Association who are Members of the Section on Ophthalmology:—During the past few years the growth of our Section has been so rapid and the number of valuable and interesting papers volunteered for our annual program has become so large that at the meeting in Columbus, two years ago, the executive committee offered certain resolutions concerning our work which were unanimously adopted. The recommendations of these resolutions having been employed with such satisfactory results at our last two meetings, they will continue in force at our next meeting at Saratoga Springs, and are as follows:

It is the decision of the executive committee that the number of papers to be read at the meeting to be held in 1902 be limited to 40. They are to be limited to 15 minutes each. Papers are to be accepted in the order of their reception and at the discretion of the executive committee.

Abstracts of all papers must be sent to the secretary before May 1, 1902.

Discussions are to be limited to 5 minutes each, and no person shall speak more than once in the same debate. The member selected to open the discussion on each paper will be allowed 10 minutes.

The officers of the Section earnestly request that abstracts of papers be sent in by April 1, instead of May 1, as the extra time is necessary in order to properly arrange the program.

It is anticipated that a large number of papers will be offered to the Section as heretofore, all of which would be gratefully received if the time at our disposal permitted of their presentation and discussion. But as the number has to be limited the officers of the Section would respectfully request those desiring to submit papers to send in their subjects at once. The exact titles and papers can be worked out later.

The officers of the Section, while not desiring to control the choice of subjects, would respectfully suggest that through letters received from members, the following general topics have been proposed for discussion: 1. Intraocular foreign bodies. 2. Indication for removal of the globe. 3. Diseases and injuries to the anterior segment of the globe. 4. Refraction and muscular troubles. 5. Punctate keratitis. 6. Vernal conjunctivitis. 7. Ocular anesthetics. 8. The connection between hepatic functions and the eye. 9. The microscopic subdivisions of conjunctival inflammations. 10. The theories of color perception, normal and subnormal, from a 20th century standpoint. 11. The newest and most rational methods of asepsis in surgical procedures, in and about the eye. 12. The passing of the so-called amblyopias and amauroses. 13. The true position of electricity in ocular therapeutics. 14. The best methods of teaching ophthalmology, with exhibition of instruments, appliances, etc.

If any of the subjects thus indicated in a general way please those desiring to write, be kind enough to so designate. If not, others may be chosen. These subjects are not intended to be exact; they are merely indicative. The Section officers hope to hear from the members as soon as possible.

It is earnestly requested that only those members intending to be personally present at the Saratoga meeting will apply for place upon the program. The officers of the Section desire especially to emphasize this point, as its observance or non-observance will have much to do with making the meeting of a satisfactory or unsatisfactory character.

Respectfully submitted, FRANK ALLPORT, Chairman, 92 State St., Chicago; C. A. VEASEY, Secretary, 116 S. 19th St., Philadelphia.

Married.

JOSE L. HIRSH, M.D., to Miss Amelia Moss, both of Baltimore, October 6.

STANLEY C. BABCOCK, M.D., to Miss Ida H. Herger, both of Buffalo, October 22.

JOHN T. MANIERRE, M.D., to Miss Mary Susan Foster, both of Chicago, October 15.

GEORGE W. WYLIE, M.D., to Miss Alma Belmore, both of Granite, O. T., October 16.

JOHN A. WESSINGER, M.D., to Miss Alice B. Walker, both of Ann Arbor, Mich., October 14.

FRANCIS CARTER WOOD, M.D., to Miss Edith Warren Sterling, both of New York, October 15.

WILLIAM E. BEASON, M.D., to Miss Lily Philips, both of Chattanooga, Tenn., October 30.

CLAUDE B. PARKER, M.D., Gallipolis, Ohio, to Miss Grace Gist, Athens, Ohio, October 16.

GILBERT E. SEAMAN, M.D., to Miss Elizabeth Sivyer, both of Milwaukee, Wis., October 29.

D. J. JENKINS, M.D., Broadway, Ohio, to Miss Ethel Colver, Summerville, Ohio, at Ohio City.

JOHN A. KILBOURN LAPP, M.D., to Miss Dorathy Sara Nice, both of Clarence, N. Y., October 23.

WILLIAM BATTLE MALONE, M.D., Memphis, Tenn., to Miss Jeane Hyde, Nashville, October 17.

CLAUDE BRADBURY PARKER, M.D., Athens, Ohio, to Miss Grace Gist, Gallipolis, Ohio, October 16.

SAMUEL W. SCHENCK, M.D., to Miss Lena Collins, both of Solomon, Kas., October 16, at Lyons, Kas.

ARMFIELD F. VAN BIBBER, M.D., Belair, Md., to Miss Rebecca Michael, at Perryman, October 16.

CHARLES A. HALL, M.D., to Miss Ethel Maud Curry, both of Cleveland, Ohio, October 9, at Richmond, Va.

HENRY MILLER BENNETT, M.D., Cheyenne, Wyo., to Miss Emily Wadhill, at Pikesville, Md., October 8.

CHARLES EDWARD HOOD, M.D., Cavalier, N. Dak., to Miss Barbara Vivian Anderson, Leyden, October 15.

JOHN F. BOYD, M.D., Paducah, Ky., to Miss Flora Steyer, Golconda, Ill., October 30, at the home of the bride.

HARRY CHENEY DYER, M.D., Gulch, Colo., to Miss Florence Whedon, Cincinnati, October 9, at the home of the bride.

EUGENE METCALF, M.D., Fennimore, Wis., to Miss Grace Lura Kightlinger, Yates City, Ill., October 9, at Chicago.

FRANK ALLHANDS, M.D., Wingate, Ind., to Miss Georgia Godwin, Sellersburg, October 8, at the home of the bride.

ALBERT M. COLE, M.D., Indianapolis, Ind., to Miss Ruth Schuyler, Pana, Ill., October 23, at the home of the bride.

ALBERT H. TAYLOR, M.D., to Elizabeth E. Grotefend, M.D., both of San Francisco, Cal., October 1, in London, England.

GEORGE H. GILMORE, M.D., Stanberry, Mo., to Miss Bessie Walker, Murray, Neb., October 13, at the home of the bride.

JOHN W. ADAMS, M.D., Walkerville, Ill., to Miss Stella Wood, Carrollton, Ill., October 10, at the home of the bride.

GAILY BARR DUNKLE, M.D., Washington, Pa., to Miss Lillie McCoy, Salt Lake, Utah, October 15, at the home of the bride.

CHARLES HERMAN CLARK, M.D., Washington, D. C., to Miss Cora Taggart, Massillon, Ohio, October 17, at the home of the bride.

CHARLES WINTHROP WILLIAMS, M.D., Minneapolis, Minn., to Miss Minnie Lyon Benham, Woodmont-on-the-Sound, Conn., October 16, at the home of the bride.

Deaths and Obituaries.

Gustavus G. Roy, M.D., Jefferson Medical College, 1857, died at his home in Atlanta, Ga., October 18, after a short illness, aged 65. He was born in Virginia, and practiced his profession in that state until 1875, when he made Atlanta his home. In the early part of the Civil war he was a captain and then a major in the line, but resigned the latter commission to become an assistant surgeon; he was acting post surgeon in charge of the hospitals at Atlanta when that city was destroyed by Sherman. He was a prominent man in his section, having served as a member of the city council for years, and having assisted in the organization of the Southern Medical College.

Benjamin H. Bradshaw, M.D., Rush Medical College, Chicago, 1861, died at his home in Salem, Oregon, following an operation for tumor growth, October 14, aged 67. He was born in Belmont County, Ohio, and served as assistant surgeon and then surgeon of the 46th Illinois Infantry, during the Civil war, being mustered out of service in 1866. He practiced at Orangeville, Ill., for a number of years and then removed to Oregon.

Charles E. Stoner, M.D., College of Physicians and Surgeons, Keokuk, 1882, died at his home in Des Moines, October 25, from typhoid fever, aged 43. He was professor of principles of surgery in the Iowa College of Physicians and Surgeons, and a member of the American Medical Association.

Charles H. Voorhees, M.D., Jefferson Medical College, Philadelphia, 1850, died at the Presbyterian Hospital, Philadelphia, October 19, as the result of an apoplectic stroke. For the past few years he has not practiced, but he was once a prominent physician of Flushing, Ohio.

Joseph Sanders, M.D., Bellevue Hospital Medical College, New York, 1892, died at Oil City, Pa., while on a visit, October 20, from typhoid fever, aged 34. After studying in Germany, he had practiced in New York since 1895, devoting himself to work on the eye, ear and throat.

Derrell B. Darby, M.D., South Carolina Medical College, Charleston, 1873, died at his home in Walhalla, S. C., after a brief illness, October 8, aged 54. He had served several terms as mayor of Walhalla and was president of the city board of health at the time of his death.

George B. Bunn, M.D., Starling Medical College, Columbus, 1883, was found dead in his office, at Mount Vernon, Ohio, October 22; death was due to heart exhaustion. During the

Spanish-American war he served as brigade surgeon with the Seventh Army Corps in Cuba.

William J. Kearney, M.D., McGill University, Montreal, 1875, died at his home in Mariposa, Cal., October 10, from pneumonia, aged 45. He was born in Canada, and for a number of years practiced in Montreal, but in 1885 he removed to California.

Leonard Latter, M.D., Detroit Medical College, 1875, died at his home in Monument Beach, Mass., October 21, aged 50. He practiced many years in Falmouth, and was well known among the summer residents along the Buzzard's Bay shore.

John R. Moore, M.D., Jefferson Medical College, Philadelphia, 1854, died at his home in Parnassus, Pa., October 12, aged 76. He was a well-known practitioner in Western Pennsylvania, until his retirement six years ago.

Albert Binder, M.D., Medical College of Ohio, Cincinnati, 1886, died at his home in Ottoville, Ohio, from pulmonary tuberculosis, October 22, aged 38. He was a member of the American Medical Association.

Lorenzo Firmen, M.D., said to have been the oldest physician in Ohio, died suddenly at his home, in Findlay, October 13, aged 94. He was a native of Massachusetts.

Jefferson M. Mason, M.D., Medical Department Arkansas University, Little Rock, 1888, died at his home in Floresville, Texas, October 12, from diabetes.

William M. Gray, M.D., New York University, 1846, died at his home in Allegheny, Pa., October 10. He formerly practiced in Menard County, Illinois.

Webster D. Gear, M.D., Beaumont Hospital Medical College, St. Louis, 1893, died at his home in Argentine, Kan., from heart failure, October 19.

George G. Rahauser, M.D., Jefferson Medical College, Philadelphia, 1866, died at his home in Pittsburg, Pa., after a short illness, aged 58.

Louis D. LaBonte, M.D., College of Physicians and Surgeons, Baltimore, 1894, died at his home in Derby, Conn., October 21, aged 31.

William Geddes, M.D., Howard University, Washington, 1884, died at his home in Washington, October 21, from paralysis, aged 50.

Guy Dean, M.D., acting assistant-surgeon, U. S. A., died in the hospital at Santa Mesa, P. I., from pulmonary tuberculosis, September 15.

Charles Edward Dority, M.D., College of Physicians and Surgeons, New York, 1884, died at his home in Brooklyn, N. Y., October 23.

H. H. Crooker, M.D., Louisville Medical College, 1895, died suddenly at his home in South China, Maine, October 15, aged 36.

Charles F. W. Haase, M.D., New York University, 1857, died at his home in New York City, after a long illness, October 15.

Samuel Butcher, M.D., Jefferson Medical College, Philadelphia, 1864, died at his home in Mauricetown, N. J., October 18.

Harmon J. Dean, M.D., Miami Medical College, 1857, died at his home in Brocton, N. Y., October 11, after a brief illness.

Miscellany.

San Francisco Plague Report.

CASE 42.—Alex. W., which was the case reported in the last communication, the man who applied for treatment at the Marine-Hospital, September 13. This man has since recovered. A pure culture of plague bacillus was obtained from fluid aspirated from the bubo.

CASE 43.—Tom Chin Fat, died September 14, at 125 Waverly Place. Body of a well-developed, fairly well-nourished Chinese male. Cervical, axillary, popliteal, epitrochlear and right femoral glands barely palpable. No existing signs of previous venereal disease. Conjunctiva hemorrhagic. In left inguino-femoral region there was a large firm mass, largest in the femoral region. Section of this swelling showed numerous hemorrhages and gelatinous edema. The lymph glands of the bubo were markedly hemorrhagic and the hemorrhage of the surrounding tissues extended into the abdominal cavity, involving the whole of the antero-lateral abdominal wall. The left iliac glands were much enlarged and hemorrhagic, as were also the mesenteric glands, which were the size of peas. Heart, muscle soft, otherwise normal. Liver, cloudy swelling, and a few areas of coagulation necrosis. Lungs, tubercular. Stomach, submucous hemorrhages. Spleen, enlarged, a few small, whitish specks subcapsular. Pulp soft, trabeculæ obliterated. Smears showed numerous pest bacilli.

CASE 44.—Mrs. Saggau, residence 628 Broadway. Died September 27. This woman was a native of Bavaria, and 52 years old. She was taken sick very suddenly on the 24th. She had been doing a washing that day and was perfectly well, laughing and talking immediately before the attack. She started into the house, but fell suddenly on the floor and was seized with a chill and vomiting. The next day she was taken to the German Hospital, where she soon became comatose and died on the 27th. Autopsy showed body of a well-developed, well-nourished, rather fat Caucasian female of middle age. Lungs: Pleural adhesions on both sides; left lung congested and slightly edematous. Right, slightly congested. Heart was flabby, walls rather thin, some roughening of the mitral valve, segments, otherwise normal. About 20 c.c. clear fluid in pericardium. Spleen was enlarged, soft, pulp very dark and swollen, trabeculæ obliterated; smears did not show any organisms. Liver was normal in size, capsule smooth and glistening; cut surface showed cloudy swelling. Kidneys showed capsule adherent, granular. Mesenteric glands slightly enlarged, dark and hemorrhagic. Lymph glands of right femoral region very much enlarged, forming a well-marked bubo. Incision disclosed hemorrhage and edema of the surrounding tissues, and the glands themselves were enormously enlarged, hemorrhagic, and necrotic. Within the abdominal cavity, the iliac glands were also enormously enlarged, forming a continuous chain with those of the inguinal and femoral regions. There was also an area of hemorrhage of the retro-peritoneal connective tissue behind the bifurcation of the abdominal aorta. Smears from the gland substance showed numerous typical plague bacilli.

CASE 45.—Lee Ming Lee, Chinese male, aged 49, cigarmaker. died September 27, at 12 Spofford Alley. Bubo found in right femoral region. The report from the autopsy is pending.

CASE 46.—Jew Hoeg Kuey, male, aged 40 years, died September 29, at 109 Waverly Place. Autopsy showed body of a well-developed, well-nourished, Chinese male, of middle age. Conjunctivæ injected. No enlargement of the superficial lymphatic glands, but the right submaxillary gland was enlarged. Buccal mucosa negative. No evidence of venereal disease. Small venereal wart on penis, but no ulceration. Heart: There was a thickening of the base of the chordæ tendinæ of the mitral and tricuspid valves; otherwise normal. Both lungs show apex adhesions and slight tubercular infection, but no consolidation or abscesses. Spleen was 14x8x3½ cm., pulp soft, rich in blood. Malphigian bodies and trabeculæ indistinct. Liver, 24x10x6 cm.; surface hobnailed. Kidneys showed chronic nephritis. Suprarenals not enlarged. There is an acute gastro-entero-colitis. No ulceration of Peyer's patches. Tonsils hemorrhagic, submaxillary and retro-pharyngeal glands enlarged. Esophageal mucosa injected. Intima of thoracic aorta markedly hyperemic. Arteries show chronic endarteritis. Smears from submaxillary gland, tonsils and spleen showed numerous streptococci and bi-polar staining bacilli. Diagnosis confirmed by inoculation.

CASE 47.—Wo Tai, male, Chinese, aged 50 years. Died October 10, at 103 Waverly Place. Was foreman of a gang at the Pacific Mail Dock. Autopsy showed body of a well-developed and well-nourished Chinese male. Rigor mortis well marked. No palpable gland except in the left inguino-femoral region, where they were enlarged into a distinct bubo. The skin over the swelling presented a bleb about 1 cm. in diameter, the

contents of which showed numerous bi-polar bacilli in smear. There were dark scars over the shins; no evidence of venereal disease. Incision of the bubo showed the glands to be enlarged, hemorrhagic and necrotic with a distinct gelatinous peri-glandular edema. The glands were largest in the femoral region. Heart valves normal. Muscle showed fibroid changes. Right auricle larger than normal and contained a clot. Lungs: Left contained a small calcareous tubercle in the upper lobe; otherwise normal. Right, normal, a few adhesions to outer wall. Spleen was enlarged, 16x3x4 cm.; showed acute splenitis. Mesenteric glands not enlarged. Kidneys injected. Liver and gall-bladder negative. Hemorrhagic glands in left iliac and lumbar regions. Smears from glands of bubo and blood showed numerous pest bacilli, but none in the spleen. Animal inoculation positive, the guinea-pigs dying five days after inoculation.

Compensation by the Valves in Aortic Insufficiency.—Drasche noted marked improvement of all the symptoms of aortic insufficiency in three patients who died within two or three years of an intercurrent disease. The autopsies of each showed that the insufficiency had become practically compensated by changes in the valve-flaps, which had altered in such a way as to remedy the defect and arrest the regurgitation more or less perfectly. He urges others to study these changes more closely in future so that their clinical manifestations may be recognized. In a general way, he remarks, every case of actual aortic insufficiency, with palpitations, edema and dyspnea at times, in which these symptoms gradually subside while the general health improves and the signs on the part of the heart grow less distinct, can be recognized as a case of compensation obtained by some retrogressive process in the semi-lunar valve-flaps, rather than due to compensation by the mediation of the left ventricle. This compensation, by a retrogressive process on the part of the valve-flaps, is most probable when the sclerosis, induration or shriveling is but partial. The details of his findings are published in the *Wien. Med. Woch.* of June 1 and 8.

Congress of Criminal Anthropology.—The following resolutions were adopted at the International Congress of Criminal Anthropology which has just concluded its sessions at Amsterdam: 1. That every child who has committed a crime should be examined by a competent physician, before being summoned into court, and those discovered to be actual degenerates should be placed in pedagogic establishments organized for the purpose to train and improve them intellectually and morally. 2. That the biological record of the criminal should be appended to the court record in every criminal case. 3. That governments should take effective steps to arrest the progress of alcoholism, such as the strict surveillance of saloons, if necessary, closing some of them, and government monopoly of the production and sale of alcohol in general. The Italian school urged that a crime should not be considered from the standpoint of personal culpability, but from that of the danger to society represented by the criminal. The physician should stand by the side of the magistrate, and the latter should be a criminologist and not a mere commentator of the text. The *Progrès Médicale* announces that the next congress will be held at Turin in 1906.

Position Treatment of Hemorrhoids.—G. Oeder recommends in the *Ztft. f. Phys. Therapie*, iv, 8, to raise the pelvis as an aid in treating hemorrhoids. A wedge-shaped cushion is placed under the lower portion of the trunk, raising it considerably above the level of the chest, thus allowing the blood in the congested nodules to escape by its own gravity. One night is usually enough. Severe cases may require the application of the cushion day and night.

Binary Syphilis.—This is a new term introduced by Tarnowsky to designate the syphilis acquired by the descendants of syphilitics after they have lost the immunity to the disease with which they were born. Binary syphilis is especially deleterious for the offspring, abortions and still-births being exceptionally frequent. He attributes the dying-out of certain tribes to endemic syphilis supplemented by this binary form.

Lime in the Treatment of Cutaneous Tuberculosis.—Christides has used a saturated solution of quicklime for eight years in the treatment of cutaneous tuberculous processes, and asserts that it transforms the focus into a simple, rapidly-healing inflammation. It destroys the morbid tissues and microbes, while it does not affect the adjacent sound skin. It can be applied in the form of a salve.—*Grèce Médicale*, June.

Societies.

COMING MEETINGS.

Medical Society of Virginia, Lynchburg, Nov. 5-7, 1901.
Oklahoma Territory Medical Association, Oklahoma City, Nov. 13, 1901.
Southern Surgical and Gynecological Association, Richmond, Va., Nov. 12-14, 1901.
Tri-State Medical Association of Mississippi, Arkansas and Tennessee. Memphis, Tenn., Nov. 19-21, 1901.
Western Surgical and Gynecological Association, Chicago, Dec. 18-19, 1901.

Lenawee County (Mich.) Medical Society.—This Society was organized at Adrian, October 22, and the following officers were elected: President, Dr. Daniel Todd, Adrian; vice-president, Dr. George Howell, Tecumseh, and secretary-treasurer, Dr. David L. Treat, Adrian.

Clinical Society of Washington, D. C.—At a meeting of this Society, October 14, the following officers were elected for the year: Dr. Walter A. Wells, president; Dr. Monte Griffith, vice-president, and Dr. J. Carlisle De Vries, secretary-treasurer.

University of Chicago Medical Society.—The organization of this Society, to be composed of members of the University faculties, was perfected, October 22, by the election of Dr. Henry H. Donaldson, as president, and Dr. Preston Kyes, secretary.

El Paso County (Texas) Medical Society.—The third annual meeting of this Society was held October 12, and the following officers were elected: Dr. Stephen T. Turner, president; Dr. Walter N. Vilas, vice-president; Dr. Junius S. Rawlings, secretary, and Dr. Herbert E. Stevenson, treasurer, all of El Paso.

Southern Kentucky Medical Association.—At the meeting of this Association, held at Bowling Green, October 25, the following officers were elected: President, Dr. W. N. Hall, Woodburn; vice-presidents, Drs. James C. Douglass, Franklin, and M. L. Garvin, Horse Cave, and secretary, Dr. Lee P. Trabue, Elkton.

Chicago Gynecological Society.—The twenty-third annual meeting of this Society was held October 19, and the following officers were elected: President, Dr. L. E. Frankenthal; vice-presidents, Drs. A. H. Ferguson and J. C. Hoag; treasurer, Dr. Emil Ries; editor, Dr. C. S. Bacon; pathologist, Dr. M. L. Harris, and secretary, Dr. W. H. Rumpf.

Iowa State Association of Railway Surgeons.—At the eighth annual meeting of this Association, held at Des Moines, October 17, the following officers were chosen for the coming year: President, Dr. Arthur L. Wright, Carroll; vice-president, Dr. Benton H. Criley, Dallas Center; secretary, Dr. Ira K. Gardner, New Hampton, and treasurer, Dr. Gilbert Baldwin, Ruthven.

New York State Medical Association.—The eighteenth annual meeting of this Association was held in New York City, October 21-24, and the following officers were elected: President, Dr. Alvin A. Hubbell, Buffalo; vice-president, Dr. William H. Biggam; secretary, Dr. Guy D. Lombard, New York City, and treasurer, Dr. Edward H. Squibb, Brooklyn. The delegates to the American Medical Association are: Drs. E. Eliot Harris, New York City, two years; E. D. Ferguson, Troy one year; Charles A. Wall, Buffalo, two years; Charles E. Quimby, New York City, one year, and Hubert H. Arrowsmith, Brooklyn, one year. The alternates are: Drs. De Lancey Rochester, Buffalo; Z. J. Lusk, Warsaw; Irving S. Haynes, New York City; L. G. Baldwin, Brooklyn, and Charles S. Payne, Liberty. An account of the meeting will appear in a later issue of THE JOURNAL.

Idaho State Medical Society.—This Society was entirely reorganized and a new constitution and by-laws adopted along the lines recommended by the American Medical Association. The officers elected were: President, Dr. H. A. Castle, Pocatello; vice-president, Dr. John W. Givens, Blackfoot; secretary-treasurer, Dr. Ed. E. Maxey, Caldwell (for two years); dele-

gate to A. M. A., Dr. Ed. E. Maxey, Caldwell (for two years); alternate, Dr. John W. Givens, Blackfoot; chairman committee on arrangements, Dr. F. J. Ledbrook, Moscow; chairman committee on legislation, Dr. O. B. Steely, Pocatello; chairman committee on nominations, Dr. R. L. Nourse, Hailey; chairman committee on publication, Dr. Ed. E. Maxey, Caldwell. Dr. L. P. McCalla, Boisé, was appointed to represent the Idaho State Medical Society on the Legislative Committee of the American Medical Association. Moscow, Idaho, was selected as the place for the next annual meeting, October 9 and 10, 1902.

Medical and Chirurgical Faculty of the State of Maryland.—A movement looking to the consolidation of the local societies with the Medical and Chirurgical Faculty of the state, as sections of the latter, was inaugurated last April, and suitable amendments proposed to the constitution of the Faculty to carry the matter into effect. These amendments lie over until the next meeting of the faculty. It was proposed to form five sections, viz., 1, clinical medicine and pathology; 2, surgery; 3, obstetrics and gynecology; 4, neurology and psychiatry, and 5, ophthalmology and otology, "and as many more as may at any time be proposed in writing by ten members of the Faculty and approved by a vote of three-fourths of the members present at a stated meeting." The clinical society took action on the above last Friday, and it was then determined to abandon independent organization; those members who are not members of the Faculty were advised to become so, and those who are members were urged to participate in the formation of the proposed sections, particularly in clinical medicine and surgery. It was ordered that all the property of this Society be disposed of, the debts paid and the net proceeds donated to the Faculty. Sixty members attended the meeting, and of 27 not members of the Faculty twenty-five signified their intention of becoming so. About $300 will be turned in to the Faculty, which will probably be put into the permanent endowment fund.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, Oct. 1, 1901.

Dr. Joseph Collins, president.

Spinal Fracture, with Special Reference to Operative Interference.

DR. GEORGE L. WALTON, Boston, presented a paper on this subject, dwelling particularly on the question of whether it was not desirable to make early operation in this class of cases the common custom. He said that there were no symptoms which would lead one to assert that the cord was or was not unquestionably crushed. In the cases of so-called complete injury one finds immediate relaxed motor paralysis and entire absence of rigidity or other irritative sign in the motor sphere. Partial injury to the cord might be indicated by slower onset of paralysis, its unilateral or irregular distribution, the partial retention of the reflexes and subsequent improvement. In fracture with total transverse lesion the area of anesthesia was generally sharply marked, and the level was materially below the seat of the lesion. The classical symptoms of complete transverse lesion certainly do not indicate conditions beyond repair. Incomplete anesthesia points to incomplete lesion of the cord; the same is generally true of anesthesia of limited or unilateral distribution. Injury to the nerve roots alone sometimes appears in the cervical region after stretching and bruising, perhaps with temporary displacement of vertebræ. The diagnosis of local concussion of the spine was still applied by certain authors to such cases. Retention of urine was the rule in all varieties of spinal fracture with injury to the cord whether the lesion involved the cervical, dorsal or lumbar cord. This probably showed that mechanical conditions prevent the escape of urine so long as the propulsive force is lacking. The symptoms referable to vasomotor disturbances are evasive and baffling. The usual rise of surface temperature might perhaps be explained by the dilatation of superficial blood vessels due to cutting off the vaso-constrictor influence from the medulla. Absence of sweating tends to fortify the theory that the principal sweat center lies in the medulla, the fibers being interrupted in their course by the lesion. Sweat secretion appears to be due to specific nerve influence conducted by specific nerve fibers and not to heat. It is now generally recognized that the knee jerk is lost in cases of complete destruction of the cord, and cases of spinal fracture constitute no exception to this rule. The superficial reflexes were generally lost or diminished in these cases, and were probably always lost in the complete lesions. The Babinski reflex was a common later phenomenon, but he would doubt its occurrence in cases of total destruction of the cord without reparative process. The local signs, such as the formation of a knuckle, were very variable, and not of much significance. Operation often shows that the apparent irregularity is of no importance. It should be remembered that a great variety of curves are found in the back in healthy persons free from injury. This statement was fortified by the exhibition of a series of tracings from the backs of healthy students in the Boston Normal School of Gymnastics. The Roentgen rays might prove of value in making diagnosis, but in his own experience this method had not yielded sufficiently satisfactory results. The prognosis in cervical cases without operation was generally grave, death usually occurring within a few days. In cases of fracture of the dorsal or lumbar region without operation the prognosis was better, but still very grave. The fatality in non-operative cases was about 80 per cent. The statistics at hand were not very reliable regarding operative cases because many unsuccessful cases were not reported. The cases operated upon at the Massachusetts General Hospital since 1870 yielded a mortality of about 64 per cent. In some quarters laminectomy was not advocated, or was even denounced. Apprehension regarding the danger of the operation had been entirely allayed, and many cases had been reported showing that laminectomy is not dangerous by reason of the weakening of the spinal column. It was doubtless true that in most cases the crush of the cord had taken place. The author was inclined to think that owing to the decided limitations of our diagnostic ability it was well to promptly resort to operation in all cases, except the moribund and those with great displacement, and give the patient the benefit of the doubt. According to his personal experience the course of the operative cases coming under his observation had been more favorable than he should have expected without operation, from his previous experience and his knowledge of the literature. The neurologist was often asked whether it was wise to open the dura at the operation, and his answer should be in the affirmative. An edematous condition of the arachnoid was apt to exist and would be relieved by such a procedure, but the chief reason was the opportunity this afforded for inspecting the cord. Of late the custom had been not to suture the dura but to leave it open. It had been the usual custom in the past to secure drainage for a day of two, but various recent operators had demonstrated that it was not at all necessary, and by eliminating drainage one could secure quicker healing and greater immunity from sepsis. In cases of grave shock it would seem to be reasonable to delay operation if only to better interpret the symptoms. Rapidity of operation was important, and the surgeon need not fear injuring the cord by the use of forceps.

DR. CHARLES L. DANA said that his own experience had led him to believe that the operation is practically safe, and that the spinal column itself is not injured by the operation. He had not had any fatal results in his operative cases, about half a dozen in all, and two of them were cases of injury in the cervical region. It was a matter of astonishment to him that such long and severe operations could be done upon these patients without sacrifice of life. He must confess, however, that the ultimate results of these operations had not been satisfactory, according to his observation. He had seen some improvement in motion and in the bladder symptoms in these cases, but that had been about all, and it was quite possible that such improvement would have occurred without operation. If by clinical observation one could be sure that the cord was crushed one should not recommend operation. This could often be done. If there was a line of anesthesia coinciding with the line of paralysis, and this co-existed with the absence of knee jerks, he would feel almost positive that the spinal cord had been cut across, although there were certain exceptional cases affecting the cervical region which did not seem to follow this rule. It seemed to him that the opera-

tion performed by Lloyd, and which the speaker had seen employed by Abbé, was the quickest, safest and most effective. The author had done a service in bringing up this subject and urging a more persistent effort to relieve this distressing class of cases. The general opinion among surgeons was that this was a class of cases which hold out but little hope of benefit from operation.

Dr. Edward D. Fisher said that he had had a number of cases of fracture of the spine under his observation, and in the main he would agree with the reader of the paper that an operation is advisable. He would do this because death rarely occurs as the direct result of the operation. Where there had been a fatal termination he felt that the same result would have occurred if there had been no operation. In two cases that had been under his observation in which cocain had been used, the operation had been done as well as under general anesthesia. In one of the cases the injury had followed a dive in shallow water, and in the other from an acrobat diving off the shoulders of another acrobat. The lesions had been about the same in each case, and because of the situation of the lesion they had been afraid to administer a general anesthetic. When the cord was touched there was a sensation of pain, but no localization, and the operation was conducted without any more shock than with general anesthesia. He agreed with the reader of the paper that it was almost impossible to make an accurate diagnosis between cases in which the cord had been partially or completely crushed. He did not believe that a lesion through the cervical region, with an absolute loss of reflexes, positively indicated that there had been a complete destruction of that region. Sometimes on cutting down and exposing the cord one observed very little change in the appearance of the cord until the dura had been cut. Even then there might be very little change because of a hemorrhage in the substance of the cord. The distribution of the sensation in almost all of these cases was irregular, so that the classical picture was rarely observed. In many cases where there had been absolute loss of reflexes there had been partial recovery; indeed, in his experience it had been the rule to see only partial recovery.

Dr. Graeme M. Hammond did not think it was always possible for the neurologist to say that the symptoms presented were positively indicative of complete destruction of the cord. In one case coming under his observation, in which a young man had fractured his fourth cervical vertebra by diving in shallow water, there had been evidence of complete injury to the cord. He had been operated upon a year or two afterward, but it was needless to say there had been no resultant improvement. In another case in which there had been an incomplete injury to the cord, and in which operation had been resorted to shortly afterward, there had been complete recovery and the man had returned to his occupation of wrestler. Within a few days he had seen a very interesting case. It had been first reported four years ago. Several bales had struck him on the back, and almost immediately he had presented the symptoms of tabes, pure and simple. He had had no reflexes and almost complete anesthesia with the Romberg symptom. He had been operated upon twelve weeks after the injury, and had made a complete recovery with a return of reflexes. He had seen this man within a few days, now twelve years after the injury, and he had then presented absolutely no symptom of injury to the cord. Such cases naturally lead one to be rather optimistic in regard to the mild cases. The fact that there was spinal deformity meant nothing, for in Pott's disease of the spine there was often very marked deformity without any spinal cord symptoms. If the symptoms presented in a given case pointed to the total transverse lesion of the cord there was nothing to be done but operate, and even this gave a forlorn prognosis. In the milder cases the operation should be undertaken as soon as possible, as here the prognosis was much better. He would operate in any cases, no matter how hopeless it seemed, because nothing else could be done, and the patient was no worse off than before. In the milder cases it was our duty to operate.

Dr. B. Sachs said that the question arising regarding operative interference in these cases was similar to the question of surgical interference in Pott's disease or in cases of tumor. The answer to this question must depend very largely upon the stage. He coulld not agree with Dr. Hammond that operation should be done because to say the least, the person would be no worse. It was still the fashion to delay surgical interference until everything else had been tried, whereas if surgical interference was to do any good it should be practiced at once. In cases of fracture of the spine, therefore, whether complete or incomplete, operative interference at the earliest stage could do no harm and might be productive of a great deal of good. The differential diagnosis between complete and incomplete crush was difficult. When the crush was complete the reflexes were almost invariably absent, whereas if there was more or less maintenance of conduction through the cord the reflexes were apt to be impaired or exaggerated according to the site of the lesion. The dissociation of sensation was, in his opinion, an exceedingly valuable symptom, as it pointed out the rather moderate involvement of the cord. He was inclined to think that it was often a root symptom and not an indication of absolute involvement of the cord itself.

Dr. J. Arthur Booth said that his experience had been limited, but he had not seen any great benefit from operation, although it should be said that operative interference had been resorted to at a late stage. It seemed rational to treat fractures of the vertebræ on the same general surgical principles as fractures in other parts of the body. In two of his cases the complete paraplegia existing prior to operation had remained unaffected, though there had been some diminution of anesthesia and improvement in the condition of the bladder.

Dr. Joseph Fraenkel referred to a case at the Montefiore Hospital of fracture of the spine. The patient had been admitted a year and a half after the accident, and had been walking around since the injury. Although the operation had been done late, it was worthy of note that three years and a half after the injury the autopsy showed that the cord had not been entirely destroyed. About six years ago he had presented to this society a paper on the differential diagnosis between complete and partial destruction of the cord. In four cases in which the reflexes had been lost the autopsy had shown complete destruction in only one of the cases. That shock alone was sufficient to destroy the reflexes was an old physiological dogma. He wished to insist that it was important to note the condition of the deep and superficial reflexes because for the maintenance of the deep reflexes it was necessary that the cord be intact, whereas this was not requisite for the superficial reflexes. The plantar reflex was the one that was not destroyed.

Dr. George E. Brewer said that there was a greater inclination in Boston than in New York for operating upon these cases. He had personally passed through various stages of opinion regarding operating on these cases. At first he had been influenced by those around him in Boston. The general rule had been when there was paralysis below the point of injury and involvement of the sphincters, to do an exploratory operation. He could not recall a single one of these cases that had been benefited by the operation, though he felt that they had all been examples of complete crush of the cord. In New York City the surgeons had been perhaps a little too conservative. Injury in these cases is either a crushing one or there is a hemorrhage within or without the cord; hence the outlook from operation was not good. The cases of hematomyelia recover without operation; cases of severe crushing injury, even with operation, do not. This seems to be the prevailing view here at the present time. Possibly some of the early successes were in cases of unrecognized hematomyelia, in which, of course, recovery would have taken place entirely independently of the operation. Last winter he had seen a girl with injury of the last lumbar vertebra. There was a sensory paralysis and complete loss of control of the bladder and rectum. Dr. Hammond had examined the case, and believing that there was no transverse lesion, had urged operation. The speaker had performed laminectomy, and had found only a

small spicule of the bone. The patient had recovered from the operation, and at the end of six weeks had regained control of the bladder and rectum. When seen two or three months after operation she had almost completely recovered. Had it not been for the advice of Dr. Hammond he would have looked upon this case as an improper one for operation. It had been his practice to introduce in these cases a very small rubber drain.

DR. A. C. BRUSH, Brooklyn, said that he had seen a number of these cases. In the past six months he had had several *x*-ray photographs made, and they had been so variously interpreted by those who had seen them that they had ceased to have any value. A case was mentioned in which great improvement had followed the removal of a spicule of bone in a man brought into the Kings County Hospital after a fall. A diagnosis had been made of fracture of the arch. An immediate operation had been done, and the arch found to be broken down, but this was not pressing upon the cord, but a fragment of the tenth dorsal vertebra. This case had impressed him with the value of operative interference as a means of diagnosis.

DR. WALTON, in closing, said that the statement made by Dr. Dana regarding the symptomatology of complete crush of the cord seemed to impeach the observations of a number of trustworthy observers. Regarding late operations he would say that if the pressure had been removed there was no use in operating, and if the pressure had existed for many months there was little prospect of doing any good by operating. Theoretically, the late operation would be useful in cases in which symptoms arose from the formation of callus on the inside of the laminæ, and the pressure on the cord, but his personal experience did not include any case of this kind.

WILLS' HOSPITAL OPHTHALMIC SOCIETY.

Regular Meeting, held in Philadelphia.

Dr. Conrad Berens in the Chair.

DR. P. N. K. SCHWENK presented a case of dislocated cataract in a 35-year-old man who had been struck in the eye some thirty years previously. The dislocation, which had taken place in the anterior chamber, and which was accompanied with symptoms of secondary glaucoma, had occurred but one week before the case was seen.

Dr. C. Berens asked if there had been any irritation of the fellow eye, which was replied to in the negative. He referred to a case occurring in his clinic. The patient, a 47-year-old man, had received an injury to the affected eye some thirty years previously. He had never had any trouble save that of poor vision until a few days before he appeared in the outpatient department of the hospital; severe attacks of pain at that time compelling him to seek relief. The globe was markedly swollen in comparison with the other eye and intraocular tension was greatly increased. There was ciliary tenderness of the good eye with a hyperemia in the optic nerve head and macular region. Enucleation was performed. Examination of the eye showed that the crystalline lens was dislocated downward and forward. The iritic tissues were atrophied, the ciliary body was degenerated, and there were the pathologic conditions of secondary glaucoma. The interesting point was the period during which such a dislocated lens can remain inert. His theory was that an exudate had formed between the lens and tissues of the iris by the formation of lymph, the symptoms of secondary glaucoma being produced by a blocking of the fluids of the eye.

DR. CHARLES A. OLIVER presented a case of dislocated lens into the anterior chamber with symptoms of acute secondary glaucoma. The patient was struck in his right eye with a boxing glove some eighteen years previously, the eye becoming blind in a year's time. The eye was never painful until four days ago. At the time of the examination, the pupillary area was blocked by a cataractous lens that was bulging into the anterior chamber. Vision was limited to a point of light perception in the lower temporal field. The lens was readily extracted through a section made through the lower periphery of the cornea with a wire loop, without the loss of any vitreous. The wound was thoroughly healed in forty-eight hours' time and there was never any reaction. The fellow eye was healthy.

DR. SCHWENK stated that he intended, as opportunity arose, to remove the dislocated lens in addition to doing the iridectomy in appropriate cases of glaucoma. This procedure he deemed desirable provided that there was not any probability of severe hemorrhage. He believed such a dislocated lens to be the causative factor in producing secondary glaucoma more frequently than any exudate and pointed out that it was nothing more than a hard foreign body in the anterior chamber.

DR. OLIVER stated that glaucoma complex arises from many conditions. In the traumatic lenticular type the eye is usually quiescent for a long period of time, when suddenly some slight injury occurs by which the more or less opaque lens is thrust into a false position, such as the pupillary area, by which stoppage of lymph flow between the chambers is produced. In such cases he has frequently performed and advised an immediate removal of the lens. His experience has been that totally dislocated lenses could remain in the vitreous chamber for years without the appearance of any gross symptoms of any kind except uveal disturbances, but should they happen to get into the line of flow of any of the intraocular fluids and give rise to lymph blockage, a precipitation of glaucomatous symptoms must as a rule be expected. He believed the plan of combination of a peripheral iridectomy with extraction of the lens a useful one in appropriate and carefully chosen cases, citing a successful example which had come under his care.

DR. WILLIAM THOMSON presented a case of exenteration for orbital sarcoma in a 79-year-old man. He also exhibited a photograph of the condition before operation, showing the enormous masses of sarcomatous material filling the orbit and protruding from it—soon following the removal of the eye some two years before. During the procedure, the tumor-mass was found mainly attached to the periosteum of the external, the superior, and the inferior walls of the orbit.

DR. OLIVER gave a brief account of a case of orbital growth—a sarcoma involving the frontal, ethmoid, and sphenoid sinuses, and the antrum—which he had removed in its entirety at one operation by breaking successively into these cavities from the orbital cavity. The socket granulated thoroughly into shape, and there never has been any recurrence of the growth or any metastasis.

SAN FRANCISCO SOCIETY OF EYE, EAR, NOSE, AND THROAT SURGEONS.

Regular Meeting, held September 26, 1901.

Complete Retinal Detachment.

DR. G. W. MERRITT presented a case of complete retinal detachment which came on suddenly twelve years ago, and has persisted unchanged ever since. In this case there was no etiological factor obtainable.

DR. R. PAYNE spoke of the therapeutic value of subconjunctival injections of normal salt solution in these cases, and stated that he had tried an injection of 10 to 12 minims in one case, but that the resultant pain was so great that he did not repeat the experiment.

DR. W. F. SOUTHARD described his method of giving subconjunctival injections, which consisted in directing the point of the needle well outward after introducing it under the conjunctiva, thus avoiding the pain and danger of infecting the capsule of Tenon. He also gave a brief history of a case of retinal detachment which he had observed in a business man some fifteen years ago. In this case the detachment had come on without any previous illness or trauma, and had remained stationary, both as to extent and as to vision, for fifteen years.

Toxic Amblyopia.

DR. R. PAYNE then demonstrated two cases of toxic amblyopia. The first case gave a history of going to bed perfectly well, and of awaking in the morning almost entirely blind, being able to see moving objects only. Two or three days later

even this small amount of vision left him, so that he could not distinguish light from darkness. Three weeks later, when first seen by Dr. Payne, he was again beginning to see objects. The veins of the fundus were a trifle full, the arteries somewhat narrowed, the margins of the papillæ somewhat hazy, the temporal halves of the discs taking on a glistening white appearance, the nasal halves retaining a pinkish appearance. Blindness was almost absolute in the nasal halves of the fields, the temporal halves possessing perception of moving objects. The patient has always been perfectly well, and there was no evidence of specific disease, diabetes, hemorrhage, nor of the taking of any drug which might produce the sudden amblyopia. His occupation of bookbinder did not expose him to any toxic influence, nor did it demand very keen vision. The patient had taken a moderate amount of alcohol for years, five or six drinks of whisky a day, and had chewed two or three small plugs of medium strong tobacco a week. This was not excessive, yet it was the only cause to be found for the amblyopia. It is probable that his field was narrowed gradually, or that he had developed scotomata previous to this attack and that the suddenness of the attack was apparent only.

The second case was one of blindness from drinking wood-alcohol. A large quantity, said to be a pint, was drunk with suicidal intent. The patient was unconscious for four days, and on recovering was absolutely blind, with widely dilated pupils. When seen ten days later he had absolutely no perception of light, his pupils were widely dilated, right papilla a trifle hazy and uniformly milky white, both veins and arteries a trifle narrowed; no other changes in the fundus. The left papilla exhibited practically the same changes, only not quite so far advanced. The patient has now been under treatment for three or four weeks; the papillæ are becoming whiter, and there is absolutely no light perception in either eye.

Dr. Southard held it unnecessary to assume any toxic agent in the first case, and reported a case in which the central vision remained good while the concentric narrowing of the fields progressed until total blindness ensued. In this case no tobacco nor alcohol had been used, and the patient was a picture of health. At no time was there any swelling of the nerve-head, and the reflexes were always normal.

Dr. Eaton was of the opinion that the changes in the fundus in the first case were possibly due to a distension of Schwalbe's (subarachnoid) space, giving rise to edema of the nerve and retina, and consequent atrophy from compression. This conjecture seemed borne out by the blur in the left eye, and the appearance of edema in the macular region. A number of men who had inhaled Columbia spirits, had complained of temporary obscuration of vision. In these cases the loss of vision is intermittent.

Dr. Merritt stated that the whiteness of the discs in the first case was much more pronounced than when he saw the case two weeks ago.

Dr. Payne stated that the reflexes in both cases were normal.

Dr. Eaton recalled the case which he presented to the Society on February 21 of this year, in which a crystal of methylene-blue and a 20 per cent. solution of protargol had been applied to an infected ulcer of the cornea, leaving a dense, bluish-green deposit on the cornea. This deposit has now entirely disappeared, and the vision has risen to 20/10.

Therapeutics.

Treatment of Pneumonia.

In his article on the treatment of pneumonia, Hare, of Philadelphia, emphasizes two statements: 1, when called to care for a patient through an attack of illness the physician should be a watchman all the time and a therapeutist only when necessity arises; 2, in all acute infectious diseases, particularly in croupous pneumonia, patients may be divided into three classes; namely, those who are so mildly ill that all they need is good care and little or no active treatment; cases so malignant that nothing can produce a cure, and a third class between the first two, which is capable of cure only when the most skilful treatment is given. We must also keep in mind the fact that pneumonia is an infectious disease and runs a definite course and no attempt should be made to influence its regular course by any line of treatment. However, complications arise in a good percentage of the cases so that the skill and tact of the physician would have to be brought into action and opportunities will be afforded for the physician to show sense and knowledge of therapeutics. In typical cases the process passes through three stages, namely, the stage of hyperemia or engorgement, the stage of consolidation or red hepatization, and the stage of resolution. In cases of delayed resolution complications are liable to arise, which require special treatment. By the use of anti-pneumatoxin, endeavors have been made to antagonize if possible the injurious influences of the diplococcus pneumoniæ on the blood and different organs. If the efforts in this line of treatment are perfected the dangers and complications arising from an attack of pneumonia will be greatly diminished. As has been mentioned, however, the combating of dangerous symptoms which arise with the complications, and the strict support of the patient's condition and strength so that the tendency to exhaustion may be withheld, must occupy the attention of the practitioner.

If the physician sees the patient soon after the chill he may have opportunity, if the conditions are properly recognized, to arrest the severity of the disease and perhaps avoid an otherwise fatal illness. The patient should be ordered to bed at once in a large well-ventilated room, and if possible a competent nurse should be employed. The following should constitute the early treatment in order to establish good elimination and relieve to some extent the congestion:

℞.	Hydrargyri chloridi mitis	gr. iii-vi	20-40
	Sodii bicarb	gr. v-x	30-60

M. Sig.: At one dose, to be followed at the proper time by a saline cathartic.

The following may be administered to relieve the pain, cough, and to promote elimination by the skin:

℞.	Pulv. opii et ipecacuanhæ	ʒss	2

Ft. chartulæ No. vi. Sig.: One powder to allay the pain, and repeat in three hours if necessary.

The following combination is sometimes used after administering the purging dose of calomel:

℞.	Tinct. aconiti	m. xv	1
	Tinct. opii camph.	ʒiss	6
	Sol. ammon. acetatis	ʒiii	12
	Syr. zingiberis	ʒiii	12
	Aquæ q. s. ad	℥iv	128

M. Sig.: One tablespoonful every two hours.

To establish renal elimination the following may be of service:

℞.	Spts. etheris nitrosi	ʒii	8
	Liq. ammon. acetatis q. s. ad	℥iv	128

M. Sig.: One tablespoonful every four hours.

The question arises and is frequently asked as to the use of bleeding in the early stages of pneumonia. There can be no question as to the advisability of resorting to this method in strong sthenic individuals of middle age and with a flushed face, difficult respiration and strong, full pulse. In such cases blood to the amount of 8, 12 or even 20 ounces may be withdrawn from the arm of the patient until the pulse becomes soft and the respirations show improvement. No such depressing treatment should be resorted to, however, in feeble asthenic patients.

Rather than resort to venesection in these strong individuals other sedative measures may be taken during the first twelve or fifteen hours of the disease, by giving the patient a hot foot bath and placing hot compresses to the chest to relieve the pain, or if the fever is high, a cold compress changed frequently is of service. Internally the following is useful to depress the circulation and produce diaphoresis:

℞.	Tinct. veratri viridis	℥i	32

Sig.: Three minims every twenty minutes until three or four doses are given.

In the second stage of pneumonia different conditions are present and the treatment must likewise be changed. In this stage a greater amount of labor is placed upon a heart which has become more or less weakened from the toxic substances carried by the blood. It is in this stage that the heart and general strength of the patient demand the attention and therapeutic judgment of the physician. The right heart must necessarily withstand the increased pressure and obstruction in the pulmonary circuit. If it can properly do its work, then the physician is doing injury to his patient by the administration of cardiac stimulants in his anxiety to do him justice. The question then may be asked: What signs and symptoms must be present in this stage to guide the physician in his treatment? In reply, we would state that the character of the heart sounds are of importance as well as the condition of the pulse. If the second pulmonic is well accentuated and the heart regular, that heart is doing as good work as could be expected, showing as it does that hypertrophy of the right heart is well developed and in excess to dilatation; in other words, the right heart is competent. Consequently, to whip a competent heart is like whipping a team of horses which are pulling their heavy loads competently and smoothly. On the other hand, when the load drawn drops into a quagmire the team may be temporarily spurred on by the whip in order that they may put forth some extra strength to successfully extricate the load. In the same way when the right heart shows that dilatation is overcoming the hypertrophy as shown by the weakening of the second pulmonic, then the heart may, with advantage, be aided by the administration of heart stimulants. As a result of this weakening other symptoms will arise, such as increased cyanosis, the change in the character of the respiration, and perhaps the mental condition of the patient. As heart stimulants, the following may be employed:

℞.	Strychninæ sulphatis	gr. ¼-½	015-03
	Spts. ammon. arom.	ʒiv	16
	Aq. camphoræ q. s. ad.....	ʒii	64

M. Sig.: One teaspoonful every three or four hours.

The foregoing may be given alternately with spiritus frumenti ounce one half to one ounce every four hours. If the cyanosis and the subjective symptoms of the patient increase, showing increased inability of the right heart to do its work competently, then a stronger stimulation must be resorted to. Digitalis has been greatly lauded in the treatment of this disease. It reduces the temperature and lessens the rapidity of the pulse, and is of use as a heart tonic whenever the pulse is of great rapidity. It may be given as follows:

℞.	Infusi digitalis	ʒiii	12
	Potassii citratis	gr. xx	1 33

M. Sig.: At one dose, to be repeated in four hours.

The great tolerance for digitalis in pneumonia has been commented upon by many writers; but we must remember, in using it as a heart stimulant in the second stage of pneumonia, that this drug should be pushed only when there are positive evidences or indications of the right heart giving out. It has the disadvantage, especially the tincture, of contracting the peripheral blood vessels and thus increasing blood pressure, and this in turn throwing more work upon the heart. It is advisable then to decrease the peripheral blood pressure as much as possible and thus negatively stimulating the heart by lightening its burden. To do this we can depend upon no better class of drugs than the nitrites, which may be administered as follows, in order to dilate the peripheral arterioles:

℞.	Spts. glonoini (1 per cent.).....	m. xv	1
	Spts. ammon. arom.....	ʒv	20
	Tinct. cardamomi comp. q. s. ad.....	ʒii	64

M. Sig.: One teaspoonful every four hours.

The foregoing prescription may be given alternately with the digitalis, or given in combination as follows:

℞.	Spts. glonoini (1 per cent.).....	m. xxv	1 66
	Tinct. nucis vomicæ	ʒi	4
	Tinct. digitalis	ʒii	8
	Tinct. gent. comp. q. s. ad.....	ʒiii	96

M. Sig.: One teaspoonful every six hours.

In conjunction with the treatment of the heart in the second stage of pneumonia the organs of elimination must receive proper attention, especially is it necessary that the kidneys be properly stimulated and encouraged to do their work properly. Danforth, in his article in the "American Text-book of Therapeutics," makes the statement that a case of pneumonia is not hopeless as long as the kidneys are in active service, otherwise a fatal result may be expected. The hepatic stimulation should not be neglected and careful attention should be given to the bowels and skin.

If the third stage or that of convalescence proceeds favorably and with no complications, treatment by drugs is unnecessary. Good digestible nourishing food and proper amount of rest will usually suffice. If resolution is delayed and the cough troublesome the following may be given:

℞.	Codeinæ sulph.	gr. vi	36
	Ammon. carb.	ʒi	4
	Aq. camphoræ	ʒi	32
	Syr. tolutani q. s. ad.....	ʒiii	96

M. Sig.: One teaspoonful every three hours.

The complications most likely to arise are, pleurisy, pericarditis, endocarditis and meningitis, which should be treated as independent diseases.

Medicolegal.

Particulars Required in Personal Injury Case.—The first appellate division of the Supreme Court of New York says, in the personal injury case of Steinau vs. the Metropolitan Street Railway Company, that it does not think that the plaintiff should be compelled to specify by a bill of particulars the injury complained of, its nature, location and extent. And while it thinks that an itemized statement of the expense that the plaintiff was put to for medical and surgical appliances was correctly ordered, it thinks that the particulars should be confined to such a statement, and that the plaintiff should not be compelled to furnish the defendant with the names and addresses of the physicians, the number of visits, and other particulars. But it holds that she might be required to state the number of weeks that she was confined to her bed as alleged in her complaint.

No Physician in Attendance at Trial of Rape Case.—In the case of People vs. Figueroa, where the defendant was convicted of having committed rape on the body of a child 6 years of age, the Supreme Court of California says that the fact that no physician was in attendance at the trial appeared to be due to the fact that no subpena was served on one. The sheriff was not the only party that could serve a subpena, and, he having neglected to make service, the defendant, if he desired the presence of a physician at the trial, should have requested a continuance until he could procure the attendance of such physician as he might have subsequently subpenaed. Not having done this, he had nothing, the court holds, of which to complain.

Temporary Indigestion and Informal Consultations.—The United States Circuit Court of Appeals holds, in the case of McClain vs. the Provident Savings Life Assurance Society of New York, that, having had "dyspepsia or indigestion at times" did not convict the insured of untruth in the sense of his contract of insurance, when he answered "No" to the interrogations in his application as to his having, or having ever had, any of an appended list of 50 or 60 diseases, including dyspepsia. Temporary indigestion, or dyspepsia at times, the court says, is too common an ailment, and not serious enough to suggest itself as a disease to one answering such a question. Again, it says that the catalogue of diseases, to each of which an interrogation point was appended in the application, was a long one, and embraced diseases of a serious character; so that, under the circumstances, the insured may well have ignored or forgotten the temporary indigestion from which he at times suffered, when called upon to say whether he had ever had,

among other diseases, the disease of dyspepsia. Then, there was this question and answer: "When and by what physician were you last attended, and for what complaint? A. Had no medical attendance." But the jury found that he had been attended by a certain physician for temporary indigestion, not material to the risk, while the evidence disclosed the fact that the physician was an intimate friend, with whom the insured was in the habit of having daily intercourse; that he kept a horse at the physician's stable; that they rode and talked together daily. The court holds that, as the physician never attended him at his house, his consultations, such as they were, as testified to by the physician himself, might well have been considered by the insured as informal and casual, and not within the category of medical attendance, as inquired about in the application.

AMERICAN.

1. **Rupture of the Bladder.**—Wyeth reports a case where bladder rupture occurred during a surgical operation from an effort to distend the organ in order to reach it by the suprapubic route. He thinks that, while the case is rare, it would be well to have a search made for similar ones. He has performed suprapubic cystotomy between sixty and seventy times and has employed as much as twenty-four ounces of fluid to distend the bladder, but never before had any trouble.

He thinks in cases where the habit of frequent micturition has prevailed for several years, leaving the organ in a somewhat permanently contracted condition, it would be advisable to be content with the difficulties and possible dangers of operating through a narrower incision with from eight to ten ounces of injected fluid rather than to run the very small risk of rupture by employing a larger quantity. In his case the patient recovered successfully.

2. **The Lane Lectures.**—This sixth lecture by Morris is devoted to the light treatment—the Finsen method—and especially its employment in lupus. He has come to look favorably on it and thinks it the best treatment for this condition, though it has its disadvantages in certain cases. He expects a still more brilliant future for the *x*-ray and the light treatment.

3. **Sanitation in the Philippines.**—Greenleaf gives an account of the conditions existing in the Philippines at the time of the American occupation, which were certainly bad, and of what has been done since that time by our sanitary authorities. Smallpox has been to a large extent exterminated. A number of contagious diseases, such as bubonic plague, typhoid and others, have been more or less thoroughly controlled. Much valuable work has been done in the laboratory. A Department of Public Health has been organized which has regulated matters successfully and the prospects for the future are in this respect the very best. When we reflect that some of the diseases found among those people are virulent in the nature of their infection, and in other tropical countries quickly develop into epidemics which are attended with frightful mortality, and that these people have been living under conditions of hardship and suffering, it is a matter of congratulation that so much success has been obtained and that the ratio of sickness in the army has been at times lower than has been observed in the tropical service of any other nation. He knows of no tropical islands in the world that have a better climate than the Philippines, but the natives have not been instructed how to take care of themselves. The sanitary measures had a pretty nearly virgin soil to work on.

4. **Mastoiditis.**—After reporting a case Dench points out the advisability of early operative interference and the dangers of delay.

5.—See also THE JOURNAL of October 19, p. 1029.

6.—See editorial in THE JOURNAL of October 19, p. 1042.

7.—See also ¶5, above.

8, 9, 10, 11, 12, 13, 14. **The Czolgosz Case.**—This issue gives a number of opinions in regard to the assassin, among them one from a lawyer who considers that the statement of the counsel for the criminal of their opinion that he was insane was unjustified as they did not present any evidence to that effect. Drs. Chapin, J. W. Durham and others remark on Czolgosz's mental condition, maintaining that he was justly convicted and that punishment should follow. Dr. F. X. Dercum does not consider the case one that calls for medico-legal decision. It does not belong to psychiatry, but to that of the psychology of crime.

15. **Co-ordination of Respiratory Movements.**—Du Bois Reymond argues for the existence of a respiratory center and points out what he considers a new reflex. When the thorax was compressed, glottic respiratory movements appeared which could not be induced in dead animals. All known sources of excitation of the respiratory centers were excluded by the conditions of the experiment, complete apnea and complete pneumothorax—or in several cases section of the vagus below the origin of the recurrent nerve—hence he thinks it must be due to a hitherto unknown kind of reflex in which the passive movements of the thorax act as a stimulus, giving rise to an afferent impulse exciting the motor center of the larynx. For sensory organs originating this impulse we must look to the sensory organs of the thorax articulations, tendons and muscles. The afferent channel must follow the course of the intercostal nerves and reach the reflex center by way of the spinal cord, the section of which, below the medulla, arrests the respiratory movements though artificial respiration is continued. The muscular sense or posture-perceptive sense of the thorax will have to be at least in part effective and the co-ordination of respiration thus shown to be exactly analogous to co-ordination of different muscles in the movements of the limbs.

16. **Ocular Affections of Childhood.**—Two cases are reported showing impaired general vitality and faulty metabolism, manifested not only by abnormality in this, but by a group of general and ocular symptoms, headache, general malaise, precarious appetite and variable temper. With these there was asthenopia, undue sensitiveness to light, inability to use the eyes with comfort, impaired acuity of vision, injected lid-borders and in both cases there was at the beginning congenital hypermetropic astigmatism. Risley thinks that in the absence of this congenital anomaly of vision the pathologic ocular conditions would not have occurred from the existing faulty metabolism. Another inquiry suggests itself: How far does the eye-strain of school children influence the general health? He thinks this hardly needs a demonstration.

18.—See also ¶5, above.

19. **Combined Analgesia.**—In order to avoid so-called mental shock in nervous persons, Fowler has been led to attempt the combination of spinal analgesia, and general narcosis with very satisfactory results. A very small amount of the general anesthetic agent is used to quiet the patient after the preliminary spinal cocainization and he thinks that the objections due to these patients being conscious of what is being done, have been quite thoroughly obviated. He is not aware that the suggestion has been offered or carried into effect of producing slight narcosis for the purpose of the spinal lumbar puncture or of combining narcosis for obliterating both the touch and sensation and the mental disturbance with the analgesic effects of spinal cocainization. Two cases are reported.

20. **Blood Examination.**—Brown reviews the advantages of blood examination, showing what different elements we observe in an analysis of the blood and gives the forms of disease in which the methods have been found of advantage. The diagnosis of typhoid fever has been very largely cleared up by the Widal reaction. There are certain forms of primary anemia in which the diagnosis is rendered possible only by blood examination. Lymphatic leukemia is by this means diagnosed from Hodgkin's disease, tuberculous or syphilitic adenitis and sarcomatosis of the glands, while splenomyelogenous leukemia is differentiated from Banti's disease, chronic malaria with enlarged spleen, tuberculosis or syphilitic malignant growths of the spleen, hydronephrosis or renal or ovarian neoplasms. In diabetes, the Williamson test would be of great value and too little has been done in connection with the Justus test in syphilis. The blood conditions in diphtheria and scarlet fever are mentioned, a high percentage of myelocytes in the former being regarded as an unfavorable sign by Engel, while several authorities regard an increase of eosinophiles in the latter disease as a favorable sign. In anemia, whether primary or secondary, the prognosis is governed by the blood examination. The study of leucocytes, especially in surgical cases, is also mentioned and in exanthemata where the presence of leucocytes point toward one or the other condition. The value of leucocyte counting in surgery is important, especially in appendicitis. Two cases are reported showing its value.

25.—See also ¶5, above.

26.—Ibid., ¶6, above.

27.—See also ¶5, above.

28. **Cancer.**—Reyburn argues against the operative treatment of cancer with the knife. He says that when an incision is made in any part of the body for the removal of a malignant growth we at once provide and lay wide open for infection every vein and lymph channel in the space operated upon. He asks the question: Can we substitute for it anything that will prevent this systemic infection? He thinks this can be done by taking advantage of a substitute for the knife, such as the electro-cautery or, in a limited number of cases, the use of arsenic or chlorid of zinc for the removal of morbid growths. He quotes the successful results of Dr. John Byrne, who utilized

the electro-cautery. The best reason for the employment of this operation is that it is absolutely aseptic and a very significant fact is noted by Dr. Byrne, namely, that when the growth does recur in cases that have been operated on, it rarely does so in the cicatrices produced by the action of the electric cautery on the tissues, indicating that the vitality of the contagium, whatever it may be, has been destroyed and rendered harmless. The objection may be urged, he says, against Byrne's method that it is not applicable for the removal of cancers of the breast or large cancerous tumors occurring elsewhere in the body. He suggests that in such cases it would be well to immediately follow the knife with the electric or thermo-cautery. Arsenic and chlorid of zinc produce layers of lymph under and around the former seat of cancer which prevent infection and he has only recently begun to use this method of treatment; he can only say that the results so far are exceptionally good and he hopes others will test them.

29.—See also ¶6, above.

30. **Surgical Antiseptics.**—Broad gives an account of experiments made with various aseptics on a pair of hands known to be infected, using first bichlorid of mercury after scrubbing with green soap and water, soaking the hands in bichlorid 1 to 2000 or 1 to 4000 for periods varying from five to fifteen minutes. In every case the culture test always developed a staphylococcus. For two weeks they worked this way without better results, then the permanganate-oxalic acid method was tried and, as with the bichlorid method, finger scrapings and pieces of the skin in culture media always developed the staphylococcus aureus. Formalin was next used, in strength varying from 1 to 4 per cent. With it results were at first more gratifying, but at no time did the growth of the microorganism fail to appear. Then followed a scrubbing with green soap with no better results. Finally the subject became disgusted and refused to be experimented on further. Here the infection had extended over a period of three months and persisted in spite of strong aseptics. He thinks this is evidence that the unprotected hands may be, and often are, a source of infection even though they are washed and disinfected. The probability of silk being a cause of infection led to some work with it to show just when it was rendered sterile by boiling. Different sizes from 1 to 20 were first infected with the pure culture of staphylococcus pyogenes aureus. They were boiled for from twenty to seventy minutes, the pieces being removed under aseptic precautions every five minutes. The water was brought to a boil before the silk was dipped in. He found, as might be expected, that the larger the silk the longer the time required to render it sterile. No. 20 silk required 60 minutes; No. 16, forty-five; No. 12, forty; No. 8, thirty-eight; No. 6, thirty-five; No. 4, thirty; and all below No. 4 were boiled 25 minutes, excepting No. 1, in which no growth was obtained after 18 minutes' boiling. This was perhaps a pretty thorough test as probably no ordinary silk could be so absolutely infected as this was, but he thinks it would be safe to use this method. Silkworm gut was also tested, but no growth could be obtained after forty-five minutes' boiling. Catgut is a matter of considerable importance. The material from which experiments were made was prepared by the bichlorid method. After the fat was dissolved it was put in a 1 to 1000 alcoholic solution of bichlorid and preserved in alcohol or glycerin alcohol. The results were fairly good and it was exceptional that any infection was found. Formalin, often so satisfactory, in a size larger than No. 2 was uncertain. The ammonium sulphate method was tried, but the strength of the catgut was much impaired. The most perfect method, in the author's opinion, is the sterilization of catgut by dry heat, subjecting the material in sealed envelopes at 300 F. for three hours, then following it with the same heat for one hour to kill any spore. Culture-tests have shown that catgut prepared in this way is absolutely sterile, and clinical experience has borne this out. Rubber gloves boiled eighteen minutes were sterile, while after fifteen minutes they still gave a culture. Experiments were made with the expired air, a mask was devised and worn for one hour, at the end of which time pieces of gauze through which the wearer had breathed were removed. Examination always gave a growth, largely staphylococci and diplococci, and an occasional bacillus. In this way we may be able to explain an occasional cause of suppuration when an assistant or observer has been present suffering from some suppurative disease of the nose or mouth.

31. **X-Ray in the Diagnosis of Calculus.**—Four cases are reported and illustrated, showing the utility of the *x*-ray in renal calculi. The results are to a certain extent negative, but Thorndike believes there is more to be expected from *x*-ray photography in this condition. If the stone contains only a small amount of urates or some other mineral salt to give a shadow, it is capable of being recognized with some degree of precision by properly experienced observers. He notices the statement he heard made at a lecture, of the impossibility or impracticability of lifting out the kidney on to the loin, and splitting it along its convex border to expose its interior to easy examination. He has not experienced this difficulty and he has used this exploratory technique in six instances and without the least trouble from hemorrhage or otherwise. In some stout people it may be impossible, but in many of average weight the procedure is not difficult.

32. **Malignant Disease of the Tonsil.**—This is a rare condition, but its symptoms and pathology are discussed by Hopkins. He finds that males are more apt to be cancerous than females. He gives the symptoms of sarcoma and carcinoma in particular and says that unilateral enlargement in an adult should raise suspicion of malignancy, but absolute diagnosis is not always easy. He reports one case where the growth removed proved to be lymphatic sarcoma, the patient dying from reeurrence three years from the time he first came under observation. Another case where the patient died within a month from pneumonia. He says that if a general rule were to be formulated for these conditions it might be: Enucleate the tumor with the finger and blunt instruments if the case is seen early and before the surrounding structures are invaded. Remove also cervical lymphatics if they are involved. If the new growth has gone beyond the stage which admits this shelling-out process with reasonable hopes of success, then external operation may be performed. In cases that are inoperable when first seen, palliative removal of the growth might be done by blunt dissection and Dr. Coley informs the author that he has treated one case with erysipelas toxins with the result that though the patient died of recurrence, it was eight years later. Massey has reported cures by the cataphoric destruction of cancer cells and though the current he uses is sometimes quite strong, it is well to know of every possible resource that may be available.

34. **Medical Secrecy.**—Cheever pleads for a change in the Massachusetts law to make it similar to that of New York in regard to medical confidences. The physician should not reveal any facts unless in case of crime where justice would miscarry if he refuses to tell the secret. Let the criminal law court decide and relieve the doctor of his obligation of secrecy.

39. **Hydrocephalus.**—After reporting two cases, in one of which there were eight tappings with an aggregate of 11 pints of fluid removed, Ewart and Dickinson offer the following provisional conclusions: 1. With due precautions the fluid of chronic hydrocephalus may be completely evacuated from the yet unclosed skull of infants, and aseptic air may be allowed to take its place. This operation may be repeated without detriment and with scarcely more risk than belongs to the usual method of paracentesis. 2. In favorable cases of moderate effusion, such as Case 2, a single operation may suffice. Continued oozing from the puncture for a few days after the removal of the tubes is not unfavorable. 3. In cases of considerable effusion an obvious indication is to relieve the brain from the weight and from the pressure of the fluid. The evacuation is facilitated by the introduction of aseptic air. In Case 1 this treatment proved to be of decided advantage. By a timely repetition of the operation a hydrocephalic infant might be enabled to carry the weight of the head, and if the treatment were begun sufficiently early, permanent damage to the brain tissue might be averted and a normal development might

perhaps ensue. 4. In large heads, while hydrocephalus persists, a considerable splashing sound is readily obtained. There is obvious risk in eliciting this sound by forcible succussion, and for the same reason any abrupt movement of the head should be avoided.

40. **Tendon Grafting.**—Tubby reports cases of talipes calcaneo-valgus, talipes calcaneus, equino-varus, calcaneo-varus, and spastic paralysis treated by tendon grafting. Of 11 cases of paralytic talipes, 6 have shown good results, and 5 fair, meaning by "good" that the results in these cases were fully attained and improvement was permanent, and by "fair" that a partial improvement was secured. In no case was there absolute failure. In four operations on the forearm for spastic trouble, the results were good in three and partial in one. He describes the technique of his operation at some length. He thinks tendon grafting has a future before it, but it will have to be used with discrimination. It is useless in cases of flail-like joint, where all the muscles are badly affected, and it should not be employed in slight cases of paralytic valgus or varus or slight equinus, in all of which section of the tendo Achillis will be sufficient. It is an operation that requires the greatest care in the selection of cases and muscles to be employed and careful watching of results of operation for years afterwards.

41. **Widal Reaction in Children.**—Thursfield has employed the test in more than 100 cases, in 42 of which he had a positive reaction. In some cases he has repeated this several times. Doubtful reactions are very seldom met with, and repetition with a different culture has not been doubtful. He has employed, as a rule, a broth culture of typhoid bacillus, generally not more than twenty-four hours old, made from a stock culture occasionally renewed from a trustworthy source. Of the 42 cases in which the reaction was positive, several were cases in which there would have been considerable difficulty without it, and there was no clinical example of typhoid fever which failed to give a reaction. He thinks, therefore, that the test is at least as reliable in children as in adults, or even of greater value. The occurrence of a previous attack of typhoid can usually be excluded in children and thus one cause of error common in the adult is avoided. Judging from the cases that he has been able to test before the end of the first week, he thinks the reaction occurs earlier in children than in adults. There is also among children a fever which, while it strongly resembles typhoid, does not run the course or present all the symptoms. He thinks it is possible that it may be an abortive typhoid, but the use of the serum reaction has shown that there are a few of these cases which are true typhoid.

42. **Syphilis.**—A number of questions were submitted to various syphilographers and their answers obtained. The questions were as follows: 1. What is the safest course in the diagnosis? 2. Has the range of remedies in syphilis increased in recent years? 3. What is the possibility of the secondary period being skipped in cases of severe tertiary lesions? 4. How far should the physician assume the responsibility of sanctioning matrimony in syphilitics? 5. What is the possibility of the transmission of syphilis in the progeny of a tertiary syphilitic? 6. Are there any cases where unequivocally syphilitic fathers have had perfectly healthy children?

43.—Dr. L. A. Duhring concludes that it is safest to proceed slowly in the diagnosis. In cases where there is a doubt, give the patient the benefit. Prolonged observation will furnish aid. There are two kinds of syphilis, the benign or mild form and the malignant or semi-malignant, the latter rebellious to treatment. The range of remedies has surely increased of late and the specific remedies not so much relied on as they formerly were. There is no doubt that in some cases secondary lesions are skipped, but the tertiary symptoms may not be severe even then; unless the case has been neglected as to treatment of the primary and secondary periods, the chances are in favor of any tertiary symptoms being mild. Syphilitic patients are apt to take the consensus of a number of physicians' opinions in regard to matrimony. In the mild cases three years should suffice to render subjects free from taint; in very mild cases even two years. The advisor must keep in mind whether he is dealing with the benign, semi-malignant, or malignant type. The same rule—the benignancy or malignancy of the disease in the parents—governs the healthfulness of children. Syphilitic fathers, after proper treatment, may undoubtedly have healthy children. The length of time they may remain healthy is a question hard to answer. In a general way, however, in mild cases, the question may be answered in the affirmative.

44.—Dr. G. Frank Lydston does not think the positive diagnosis of primary syphilis is so frequently possible as is generally supposed. There are many shades of variation between the classic type which the expert physician can diagnose with his eyes shut and the slight parchment induration which often resembles slight inflammatory induration. The mixed forms are apt to give trouble, and a mistake may occur in the diagnosis to any one, however expert. He does not think the therapeutic remedies have been very much enriched by any reliable remedies, but there have been some modifications of treatment which have been of great value. Among these is the hypodermic use of mercury, and one of the most valuable adjuncts in his experience is potassium chlorate in full doses. The exhibition of this drug in alternation with mercury is of great value, not only on account of the lessening of mercury, but for the curative action of the chlorate itself. He is skeptical as to the secondary period being ever skipped, but it may be slight and not noticed. As regards marriage the physician should assume no responsibility whatever, but should tell the patient that we have no known means of pronouncing a patient permanently cured. He is skeptical as to the possibility of transmission of syphilis to the offspring of tertiary syphilitics. He believes that in a large number of cases syphilitic fathers may have perfectly healthy children. All these cases, however, had late syphilis. He does not know of a case begotten in the first year of syphilis which was healthy.

45.—Dr. Orville Horwitz answers the first question by saying: Wait for the first manifestations of the secondary symptoms. The second question he answers in the negative. The third, that in some irregular types the secondary period is absent. To the fourth question he says that if the syphilitic has had three years of active constitutional treatment and is then kept under observation for one year and no signs of the disease have appeared, marriage may be advised with safety. Children born of parents suffering from benign syphilis are healthy unless the parents are affected with the irregular form of the disease, when both secondary and tertiary symptoms are present. The danger of transmitting the disease rarely reaches the vanishing point until about six years after infection. Fathers suffering from tertiary syphilis may have healthy children.

46.—Thomas G. Morton advises that the safest course of diagnosis is to consult a competent medical man and thinks that the range of remedies has not materially increased. He believes that the secondary symptoms may be slight and unnoticed, but the disease follows a regular course. The physician should assume no responsibility in sanctioning marriage in these cases, and any person who has been infected might be expected to transmit more or less taint. So far as his observation goes apparently healthy children have resulted from the marriage of syphilitics, but at any time the disease might appear in them.

47.—Edward L. Keyes advises caution as to the diagnosis, believes that the therapeutic remedies have increased and that the secondary period can be skipped absolutely, but in most such cases it is only overlooked. He thinks marriage can be sanctioned five years after infection, if there has been thorough treatment during these years, and believes that syphilis is never transmitted, as such, to the third generation. Fathers infected with late syphilis may have healthy children.

48. **Unrecognized Chancre.**—Gottheil believes that attention to the following points will prevent error in the diagnosis in the vast majority of cases: 1. The presence of tumor as the original lesion. 2. The painless and indolent character

of the tumor. 3. Coincident with its appearance, or very shortly after, there is a peculiar stony induration of the nearest lymphatic glands. This is to be carefully distinguished from the later general adenopathy. 4. The time a chancre takes for its development and retrogression is only a few weeks. Tuberculous infection takes months, and cancer even years for its development. 5. Early in the history of chancre, but later in the local adenopathy referred to, there occur unmistakable signs of general infection, such as pain, especially nocturnal, in the joints, synovitis, lymphadenitis, exanthems, etc. They are frequently slight and fugacious, and any patients presenting a tumor with these characteristics should be carefully and systematically examined at short intervals for their appearance.

50. **Management of Syphilis.**—The insidiousness of the disease is insisted on by Fuller, who remarks that the unexpert may make quite a percentage of mistakes in diagnosis. The patients dreading it at first, soon come to slight the trouble and may reject their doctor's diagnosis and neglect treatment, or they may overdo the matter. Those who have suffered from the secondary manifestations are generally convinced and stick faithfully to treatment, and escape later severe trouble. In cases of locomotor ataxia, for example, he has observed it is remarked that the early symptoms of the disease were trifling and the treatment correspondingly light and inefficient.

51. **Treatment of Syphilis.**—Fifteen years ago Greene commenced to treat his syphilitic patients practically in the following manner: "All constitutional treatment, except the expectant, was postponed until the appearance of erythema—the initial lesion being treated generally by the mildest of local mercurial preparations, such as the plaster, or weak solutions of bichlorid or black wash. Then came a vigorous administration of the proto-iodid internally, tonics and liberal diet, ordinary rules of hygiene being enjoined. After the disappearance of the erythema, a course or two of inunctions were followed by a return to the proto-iodid internally. This treatment was maintained continuously for several months. Then there were intermittent periods in which no treatment was administered, alternating with more inunctions, or with mixed treatment—that is, mercury and iodid combined; or inunctions externally and the iodid internally. The patient was kept under observation for a period of two years, and at the end of that time considered practically cured. Cases which were extremely anemic, or did not react well to mercury, were given a liberal supply of tonics for a few weeks, such as iron, quinin and strychnia, in combination with the appropriate treatment of any local lesions on the skin or mucous membranes, until the patient had become strengthened and the return to mercury would not generally be followed by distressing effects. He still follows this method to a great extent. He has found, however, that neurasthenia is not only caused by but may be already existent in syphilitic subjects and require more care and attention than the disease itself. He would, therefore, use cold baths, douches, static electricity and other methods, dietetic and otherwise, for this complication. Iron in some cases of non-irritating type, glycero-phosphate of lime, and so on, are not to be despised. Blood examination is important in every case. He believes now that the constitutional treatment should be commenced as soon as the patient and physician are both sure that they have an attack of syphilis to combat. Individuals who have been heavy drinkers do not thrive as well on mercury given internally as by administration by means of baths, or inunctions. Gout, rheumatism and tuberculosis are all rendered more acute by a syphilitic infection. The excretory organs must be kept in a good condition, especially the skin, and Greene advises some form of exercise, severe enough to induce perspiration, followed by a shower bath or a light Turkish bath once or twice weekly, or mercurial fumigation. He believes that the result of treatment of late years is better than that of earlier times, as we see fewer people disfigured. Patients who have suffered from syphilis should be advised to keep up their tissue vitality for the rest of their natural life, even after there have been no symptoms, and should devote considerable time and attention to exercise, baths, etc., to keep their excretory organs in the best possible condition.

52. **Pulmonary Syphilitic Disorders.**—Gwyn describes the manifestations of syphilis in the lungs, pleura, etc. Interstitial pneumonia may occur in these cases, similar to the same disease from other causes. The diffuse suppuration of the lungs affects usually the middle portion, rarely involving the apices, and advancing toward the periphery. In early syphilis there may be a catarrh or fibrinous pleuritis. The later pleural changes are gummatous and peripheral pleuritis occurring with interstitial pneumonia. Syphilitic bronchial affections may exist alone or may be associated with other lesions, laryngitis, etc. In hereditary disease, while pneumonia of the fetus is usually found in still-born infants, structurally it resembles the diffuse pneumonia infiltrations. The rules of specific treatment in general will apply to treatment of pulmonary affections.

54. **Diagnosis and Management of Syphilis.**—Cabot emphasizes the following points: 1. Importance of never treating a suspected case of syphilis with mercury till sufficient evidence of the disease is present to overcome all doubt in physician's and patient's minds. 2. Dangers of syphilis: its relation to the patient's future and the community at large. 3. Length of treatment: its importance and the prognosis. 4. The relation of the disease to marriage, and the begetting of healthy children.

55. **The Curability of Syphilis.**—The conclusions deduced by Gottheil are as follows: 1. Syphilis is a curable disease, and may even, with restrictions, be called a self-limited one. 2. While the cure of a given case can never be affirmed with scientific accuracy, the chances of its being the fact after a certain time under proper treatment are so great that it may properly be claimed to have been effected. 3. Practically, a patient who has been properly treated through the active stages of his disease, and who has had no manifestations of it for several years thereafter, may be regarded as cured, and may be told so.

67. **Spinal Curvature.**—Phelps gives the results of dissection in cases of spinal curvature and points out what he thinks are the mistakes in the treatment. He holds reliance in gymnastic exercises for this condition one of the greatest fallacies that have ever been offered, and that the various machines that have been devised have no possible effect on the curvature and rotation per se. The only possible good they can do is to assist in holding up the spine, but so long as the ribs are bound together by contracted intercostal muscles, that force can be of but little avail. The only possible mechanical treatment is the using of force under anesthesia that would be unendurable without it: breaking away adhesions or dividing some by the knife; but he has never yet succeeded in straightening a growth in which bone change has taken place. He believes in gymnastic exercise, breathing exercises to expand the chest, elevate the ribs and change the form of the thorax; but these should be performed while the corset is on. They should be light and not severe gymnastics. He believes the aluminum corset is the best substitute for many of the braces and corsets now worn in Pott's disease and lateral curvature, and points out the advantages.

78. **Tuberculosis of the Internal Genital Organs.**—Duenas reports a case with elaborate microscopic examination in which there was peritoneal tuberculosis with involvement of the ovaries and tubes in a child eleven years old. The diagnosis was made largely on the lymphatic constitution of the patient, unfavorable hygienic surroundings and antecedents of the disease; against this was negative hereditary antecedents. The symptoms were peculiar. The stage of anasarca, accompanied by increase of urine at first, suggested the idea of a transient nephritis; then followed a period of four months with fever, diarrhea, emaciation and later three months of hypopyrexia, beginning with hypogastric pain and abdominal enlargement. The case shows that in the absence of a bacillar purulent vaginal discharge it is not even possible to

presume the presence of primary tuberculosis of the female genital tract in children. The operation that was performed was followed by apparent recovery.

79. **Respiratory Failure in the New Born.**—Snow reports two cases and one taken from the literature in which children born after normal labor, and apparently in perfect health for a few days, were taken suddenly with failure of respiration associated with opisthotonos. In one of his cases the child recovered, also in Dr. Keith's case, which is reproduced. He does not explain the condition, and thinks that we have here a new disease as yet unnamed. It may be that there is some transitory but powerful infection of the medulla. He thinks the cessation of breathing is due to some strong inhibitory impulse from the respiratory centers in that region. While the opisthotonos would suggest tetanus, the other characteristics of that condition are not present. In the case reported by Dr. Westcott that recovered, it was suggested that it was due to pressure on the medulla, the rapid clearing-up suggesting congestion or slight edema.

81. **Congenital Heart Disease.**—From a study of some thirty-two cases of congenital heart disease Morse considers the following points: 1. The considerable proportion of cases in which the cardiac lesion was discovered during a routine physical examination, there having been no symptoms referable to the heart. 2. The length of time which the condition may exist without the development of any symptoms, several cases having shown no symptoms at three and four years of age. 3. The comparative mildness of the symptoms in cases of patent foramen ovale. 4. The recovery from lesions which from physical examination were apparently the same as those in cases which resulted in chronic invalidism or death.

91. **Cerebellar Tumor.**—In a case here reported by Gordinier the general symptoms were double optic neuritis passing on to atrophy, intense and continuous headache, vomiting, dizziness, slow cerebration and gradual loss of memory. The focal symptoms were an ophthalmoplegia interna, double incomplete external ophthalmoplegia, marked cerebellar gait, a coarse tremor of the hands and ataxia in the left leg, together with choreiform movements. The autopsy showed glioma involving the central part of the superior worm, which in its growth forward into the mid-brain region destroyed the superior medullary velum, the interior of the posterior quadrigeminal bodies, especially the right, the central gray matter surrounding the aqueduct of Sylvius, the dorsal part of each ocular nucleus as well as the nuclei for the trochlear nerves, the tegmentum in the region of the red nuclei, and the superior cerebellar peduncles at their point of decussation, involving most, the fibers coming from the left side. He analyzes the symptoms with special reference to Nothnagel's statement that in tumors in the region of the corpora quadrigemina, the chief localizing symptoms would be a cerebellar gait and double ophthalmoplegia, especially involving the superior and inferior recti muscles. Gordinier considers his dictum too dogmatic and holds that the distinction between corpora quadrigeminal and cerebellar tumors is at times absolutely impossible.

99.—Ibid., p. 1731.

104. **Tendencies in Hospitals for the Insane.**—This article contains some remarks by Robbins as regards prevailing tendencies in asylums. He thinks there is not much liability to dangerous radicalism, but that the tendency is rather to ultra-conservatism. Advances make their way rather slowly in these institutions. The trained nurse, who has become so indispensable in general hospitals, makes her way slowly here, but she must add to the requisitions of the general nurse, the ability wisely to control unreasonable people. He points out the needs of the asylum nurse and remarks that it is to be feared that the nursing force in these institutions is not equal to the demands. There is the danger of too much commercial spirit in these institutions; wages rather than high ideals of the service are too much regarded. As regards pathologic laboratories, he thinks they may be overestimated in asylums. The average asylum physician has neither the training nor the time for such work. A central laboratory, as in New York, would probably result in better original work. The cases, however, should be thoroughly studied in the asylum, and rigid and systematic diagnosis should be made. Another thing that is slow in coming in asylums, is a properly equipped operating room with modern instruments and appliances. Physicians should keep well in the current of medical progress. The medical staff is usually made up of young physicians who have just served a term in the general hospital. They are required to be on duty day and night, Sundays and weekdays throughout the year. The work is not usually so hard and exacting, but it becomes monotonous, and as a rule they are not allowed to marry, which deprives them of the comforts and enjoyments that come from a home life. The best class of men is apt to avoid these institutions, and others that do come see that their stay can be only temporary and become indifferent or restless and discontented. The mechanical promotion according to seniority is also discouraging. Isolation and the lack of necessities for improvement tend toward deterioration. Association with the insane is not likely to do any mischief; it is the cutting off from external stimulating influence. He remarks that two opposite views are held as to how to get employes to render the most service. One class of superintendents have recourse to the introduction of frivolous amusements for their employes, etc., while others find that efficient services are only to be expected from the sincere and thoughtful, and would encourage moral and religious influences and employ only rational and elevating recreations. He thinks the latter plan the best.

105.—See abstract in THE JOURNAL, xxxvi, p. 1731.

106.—Ibid.

113.—This article has appeared elsewhere. See THE JOURNAL of September 28, ¶130, p. 868.

114. **Blood Antisepsis.**—The method here suggested by Taylor is the use of hydronaphthol, which he considers innocuous when given in a solution of olive oil in doses of 12 gr. daily. In no case was there any untoward effects from the drug and there seemed to be a decided benefit in the symptoms. He has used it in acute phthisis, in typhoid and in other diseases. The ideal method of administration would be intravenous injection in whisky or 50 per cent. alcohol, slightly warmed. It could then perhaps render the blood plasma actually germicidal, but this method is seldom practicable or convenient, and he would not recommend it excepting in emergencies like pyemia or septicemia. The hypodermic method is applicable, though it may produce some discomfort. But the most convenient and pleasant, though not quite so efficient a method is, as he suggests, in a solution of olive oil. He thinks that with prolonged administration the medicine will produce no unfavorable effects and is, therefore, a practicable method of blood antisepsis, pre-eminently in tuberculosis. It is also useful in typhoid, in pneumonia, in malaria as a substitute for quinin, in diphtheria together with antitoxin, in erysipelas by local injection, and in cerebrospinal meningitis, pyemia, septicemia and general septic infection.

115.—This article has appeared elsewhere. See abstract in THE JOURNAL of August 24, ¶40, p. 531.

117.—See abstract in THE JOURNAL of September 28, p. 854.

128. **Ligature of the Innominate Artery.**—Curtis gives a report of cases in which he employed a modification of Milton's method of exposing the anterior mediastinum by splitting the manubrium only instead of the whole of the sternum, and then dividing the bone transversely at the lower border of the first intercostal space. He gives the steps of it in detail, for which the reader is referred to the original.

130. **Foreign Bodies in the Abdomen.**—Schachner has investigated the subject of foreign bodies left in the abdomen and discusses the subject in its pathology and medicolegal relations. He reproduces the account of Kosinski's case where artery clamps were left in the abdominal cavity after laparotomy, from which a lawsuit resulted, ending, however, in

the acquittal of the surgeon from the charge of malpractice. He corresponded with surgeons throughout the country and reproduces in his article answers to a number of his queries which show how frequently such accidents may occur. He also mentions the recent Baldwin case in Ohio, where we believe suit is still pending against the hospital, though the surgeon has been acquitted.

132. **Pneumococcus Arthritis.**—Allen and Lull report a case of pneumococcus arthritis involving the knee-joint and also three cases that have been collected by Cave in which the pneumococci were obtained in pure culture as in his own case. Local infection with pneumococci apparently judging from these cases, three of which were fatal, is a very dangerous condition, and he thinks that possibly it may be a more frequent infection than has been supposed.

152.—See abstract in THE JOURNAL of September 14, p. 714.

153. **Surgical Tuberculosis.**—Thistle pleads for medical treatment in the proper toning-up of cases of surgical tuberculosis and believes creosote by far the most useful of the therapeutic agents at our command. In 10 cases he has had marked results by not neglecting this. He does not see any reason why patients with local tuberculous disease of the bones should be barred from receiving medical as well as surgical treatment, and he reports a case of tubercular disease of the elbow treated by splints, tonics and creosote with good results.

154. **The Systematic Doctor.**—This article which, as it has no author's name attached, seems to be an editorial, points out certain things which it thinks would aid the practitioner in various ways. For instance, keeping better records, and system of tabulating facts and cases, putting down charges correctly and on time. It suggests the card-index system as a valuable aid, and holds the doctors miss it badly by their slouchy methods in presenting accounts. The monthly statement would be a better plan, but it is unusual to find a doctor who sends one out. It is a good plan to keep a dead-beat list, and the establishment and observance of regular office hours will be found advantageous even for the cross-roads doctor, who will save hundreds of miles of travel and make many extra dollars. The careful examination and study of cases, notes taken at the time and industry, are what lead to success. Whenever there is any important lapse in memory look it up again. Keep one's self fresh as to the facts of anatomy and physiology and other branches of medicine by study of references of this kind. The card-index can be used to advantage in this connection.

157. **Ureter Catheterism.**—Various methods of separating the urine from the kidneys are criticised by Lewis, who finds all the previously devised instruments for ureteral catheterization unsatisfactory and the Harris segregator objectionable, as it produces in many cases unbearable pain and is erratic and unreliable. He describes and offers to the profession a cystoscope of his own device, which he thinks has advantages over any previous one, both in its actual use and in its facilities for sterilization. Besides its value in catheterization he found it also of value in cystoscopic examination of the bladder.

159. **Syphilis.**—O'Donovan questions the method of waiting for the secondary symptoms before beginning active treatment. He thinks syphilis can be best treated as soon as it can be diagnosed, and that if this plan were followed the later nervous complications which are now becoming so common would not occur.

166.—This article has appeared elsewhere. See THE JOURNAL of July 20, ¶117, p. 224.

167. **Syphilis.**—After noticing the different characteristics of syphilis, Wolff holds that the factors which influence its severity reside both in the seed and soil, but vary in type with the nature of the soil and the quality of the virus. The nature of the soil depends on the physical condition of the infected, his health, race, age and sex. The quality of the virus depends on the dilution from frequent transmission and attenuation by mercurial treatment continuously or intermittently carried out along the links of the antecedent chain. Attenuated virus in healthy soil means abortive or benign syphilis, while with the possible exception of racial immunity or resistance, depraved soil and unmodified virus means severe or malignant syphilis. He notices that with the pure-blooded negro syphilis is very mild and is almost self-limiting, and later lesions of bone and viscera are rarely ever seen, while in the mixed blood or mulatto the ravages of the disease are very great, not only on the surface but in the internal organs. This he thinks is largely due to inherited resistance in the negro, which is less in the hybrid, the environment of each being the same.

168. **Ridge Fever.**—This form of continued fever or ridge fever, which has been described as peculiar to parts of South Carolina, is held by Moore to be a form of typhoid. Quinin seems to have little effect on it; he therefore thinks it can not be a malarial disease.

FOREIGN.

British Medical Journal, October 12.

Chronic Diseases of Joints Commonly Called Chronic Rheumatism, Osteo-Arthritis, and Rheumatic Gout. ARCHIBALD E. GARROD.—Garrod discusses here the real relations of rheumatoid arthritis and describes its symptoms. He thinks there are two well-defined groups. One is characterized by the frequent implication of the small joints of the hand and feet and by the symmetrical distribution of lesions, and the conspicuous degree of secondary muscular atrophy. The large joints suffer as well as the small, and those of the spinal column and the temporo-maxillary articulations are implicated in a large proportion of the cases. The hands and wrists are often the parts earliest attacked. In the fingers the first row of the interphalangeal joints usually suffers most, and the terminal joints usually escape. Arthritic muscular atrophy is early seen. The onset of the disease is apt to follow the action of debilitating causes, and of late years especially influenza. Its progress may be slow or rapid. This may be arrested at an early stage and a large degree of recovery may ensue, or it may advance until every joint in the body has become involved. The general health is liable to be impaired to various extents by anemia, etc. Visceral lesions are rare, but albuminuria is occasional. The softer structures of the joints seem to be chiefly involved. Our knowledge of the morbid anatomy is very scanty and it has so little fatal tendencies that the opportunity of examining the joints in the early stages are very rare. We can have no more valuable contribution to this discussion than a careful description of the postmortem appearances in an early stage of this kind of rheumatoid arthritis. It is most frequent in female patients in early or middle life and less frequent in men of the same ages. There is a form of disease met with in children with very similar articular lesions and a fatal result is not rare. In the second group of cases the sufferers are mostly female. With these the articular lesions tend to be symmetrical, and the small joints are usually early attacked; the patients are usually more advanced in life, and there are well-marked differences in the articular lesions. The terminal joints in the fingers are here very liable to be attacked, and especially the carpo-metacarpal joint of the thumb. Constitutional disturbance is practically absent; pain is often slight. The progress of the disease is usually slow; many joints become involved. The enlargement is evidently due to bony outgrowth. Fusiform swelling is entirely wanting. Muscular atrophy occurs, but it is usually less capricious than in the other type. The postmortem appearances of the affected joints conform closely to the classical description of the osteo-arthritic changes. It may occur in early life, but it is more characteristic of advanced age. There are still other complications, but he thinks these two are the most distinct, and the question arises whether they represent two distinct diseases and whether we should not use the term rheumatoid arthritis for the former and osteo-arthritis for the latter. The question also arises whether there is no direct relationship of acute rheumatism and gout to these cases, but he is inclined to favor the idea that this rheumatoid arthritis had its characteristic features from the beginning, though it is not easy to assert

that true rheumatism plays no part at all in its causation. Endocardial lesions have been reported as occurring in a large proportion, but he thinks it is not an event to be anticipated. As far as bacteriologic evidence goes it would point rather to rheumatism being a distinct condition. If there is a relationship with gout it is with the nodular and osteoplastic form, but in the majority of cases no evidence is forthcoming of a gouty origin of the changes in the question. There is some support to the infective theory of the disease, but it is not satisfactory. The main principles to be followed in the treatment are to find out whether there is a debilitating influence present and to relieve it; any unhealthy condition of the mouth and gums should be looked for, as it has been held by some that infection from unhealthy gums plays an important part in the causation of disease. The diet should be as nutritious as possible and meat should not be cut off. Stimulants are in some cases beneficial rather than otherwise when taken in suitable form and quantity. We should try to keep up the patient's strength, and maintain as high a level of general well-being as the condition admits. On the same principle it is desirable to give tonic drugs, cod-liver oil, iron and arsenic provided they do not upset the digestion. Fresh air and such exercise as can be taken without injury to the joints are beneficial, but he thinks massage and passive movements of the joints often do more harm than good. As regards balneotherapy, he thinks that the douche-massage of the kind given at Aix-les-Bains and many English watering places. is preferred to other modes of administration, and especially to deep-immersion baths. In most cases the disease is arrested under treatment and fresh joints are not involved, and if the condition has not already done too much damage to the articular structures, something nearly approaching complete recovery can sometimes be attained. In the discussion that followed, Dr. E. J. Cave rather favored the microbic origin of the condition and reported cases which seemed to him to indicate this. He thinks, however, it is safer to hold one's opinion in suspense.

Peripheral Neuritis in Beer Drinkers; Its Precise Causation and Diagnosis. Ernest Septimus Reynolds.—Reynolds describes the neuritis described in beer drinkers, which has been so prominently before the medical profession of late, and raises the question whether alcohol neuritis may not be due to arsenic, as was proven to be the case in the Manchester epidemic. There is the possibility, of course, that both may produce a neuritis and that the two poisons act in combination, but he believes ethyl alcohol alone never has done it when given experimentally to animals. He can not bring himself to believe that every case of alcoholic neuritis recorded has only been caused by arsenic, but thinks large numbers have been due to the combined action of the two poisons, and that arsenic in an alcoholic subject is much more virulent as a producer of neuritis than when taken alone. He suggests also that beri-beri has been diagnosed for states really due to arsenical poisoning.

New Methods and Results in the Bacteriologic Investigation of Fetid and Gangrenous Suppuration. Edward Rist.—The author describes his own method of bacteriologic analysis of pus, especially for anaërobic germs. It is that of Pasteur. The pus is diluted in several tubes containing to a height of about 4.5 in. liquid sugared agar, which is afterwards allowed to get rapidly solid, by plunging the tubes into cold water. The upper part of the agar column only can absorb oxygen, while the deeper layers are totally deprived of it. The tubes are put into an incubator and the colonies of anaërobic germs appear in the depths of the agar, where they can be withdrawn by means of aspiration through a clay pipette, without destroying the tubes and without preventing the later growing colonies from appearing in their time. Pure cultures of each germ are easily obtained by this system, and each species, once isolated, can afterwards be inoculated on various liquid and solid media. This method avoids the use of the air-pump, of hydrogen or pyrogallic acid, and enables the bacteriologist to make in a very short time a great number of dilutions, which is, of course, absolutely impossible with the other methods. He has studied and described several species of anaërobic germs which seem to play a very important part in human pathology; bacilli racemosus and bacillus fragilis seem to be the most active agents in appendicitis and pulmonary gangrene. These are also found in putrid pleurisy and otitic infections, together with staphylococcus parvulus and micrococcus fetidus. There are other species, however, described by him and his co-workers, and one of the most interesting is a certain bacillus bifidus found by Tissier in infants' intestines, where it has been taken for bacterium coli commune, and which it seems ought to be considered the normal microbe of the infantile intestine. Sometimes there are only anaërobic germs in the pus, sometimes they are mixed, but the author's researches entitle him to the view that whenever there is a fetid suppuration or an active gangrenous process, anaërobic germs are at the bottom of it. He thinks the presence of such germs in pus points to a severe form of infection, whereas the spontaneously curable forms are generally caused by the ordinary well-known pyogenic cocci.

Treatment of Phthisis by Electric Currents of High Frequency and High Potential. Chisholm Williams.—The treatment of pulmonary tuberculosis by high frequency electric currents has, as Williams claims, given very striking results. In 43 cases, all of them over a year's duration and picked by other medical men for the severity of their symptoms, 42 gained in weight and loss of all symptoms, except in a few where slight cough remains and a few bacilli may be found occasionally. The method is described. The Tesla method differs from the ordinary dynamo of the different coil currents in the indefinite alternations and high electromotive force. In the first, or auto-conduction method of the author, the patient is placed in a large solenoid and currents are induced in the living body, from which sparks may be drawn, though this is not needed in actual practice, but just for demonstration. He found that general electrification was better than local and the methods of treatment are of three kinds: 1. Auto-conduction; 2, Auto-condensation, in which the patient lies on a couch in or under which is a large sheet of metal that forms one armature of a condensor, and the patient, by means of suitable handles, the other. In this way currents of from 300 to 400 milliamperes may be safely passed through the body. The third method is by the resonator of Oudin; a solenoid, one end of which termintes in a metal sphere or other shaped terminal, and the other end terminates in the outer coats of the jars connected to secondary terminals of coil. From this can be drawn a long brush discharge similar to the static breeze, but absolutely painless, and of far greater power and intensity. This method can also be used locally. He describes the various symptoms as observed under this treatment. There is a vast increase in the number of bacilli, though a later decrease, and they tend to become clumped and become irregular and small, staining with extreme difficulty. The breathing, pulse, etc., are rapidly affected. In the first month he gives the application sometimes daily, in the second every other day, and in the third twice a week. In several of his cases ordinary occupation was resumed after the first month or so of treatment.

Diagnostic Value of Tubercle Bacilli in Relation to Phthisis. D. J. A. Chowry-Muthu.—A summary of the author's conclusions are as follows: "1. The presence of tubercle bacilli in the sputum proves conclusively the existence of pulmonary tuberculosis. 2. There are other agents beside tubercle bacilli that cause destructive diseases of the lungs, producing symptoms similar to those of tuberculosis. 3. The absence of bacilli in a case of pulmonary disease does not prove the absence of tuberculous disease. 4. It may be due (*a*) to simple phthisis; (*b*) to faulty methods in the examination of sputum; (*c*) to very early tuberculosis of the lung; (*d*) to very late tuberculosis where signs of fibrosis are evident. 5. A correct diagnosis becomes extremely difficult where bacilli can not be found on several examinations, in which case the history, physical signs, and symptoms should be more relied upon than the negative evidence. 6. In all cases of pulmonary diseases a systematic examination of the sputum is of utmost

importance both for negative and positive evidence of bacilli.

Treatment of Chronic Bronchitis in the Elderly and Aged. Harry Campbell.—The three points of Campbell's article are summed up by him as follows: "In treating chronic bronchitis in those past middle life the toxicity of the blood should be kept as low as possible. The air breathed should be pure and nasal breathing insisted on. The diet should be a bare sufficiency, and alcohol and malt indulged in sparingly, or not at all. Every ounce of superfluous fat should be got rid of. The general health should be maintained at the highest possible level. A vigorous circulation should be maintained. Every precaution should be taken against breathlessness. Breathing exercises should be resorted to in order (among other things) to preserve the mobility of the thorax."

The Lancet, October 12.

Present Treatment of Inoperable Cancer. Alfred Cooper.—The various methods of treatment of inoperable cancer are reviewed by Cooper: Coley's serum, anti-cancerous serum, oöphorectomy, thyroid feeding, lymph gland extract recommended by Snow, the Roentgen rays, Finsen's light treatment, injection of various irritating substances, acetic acid, alcohol, methyl violet, cobra venom, artificially produced suppuration as by turpentine or arsenious acid, or calcium carbid recommended by Etheridge, and electricity. Among the drugs he speaks in most favor of is chelidonium as having the most evidence of its efficiency. As a result of his review he offers the following conclusions: "1. That in cases of inoperable sarcoma, more especially the spindle-cell variety, the patient should have the option of Coley's fluid given to him, since a certain number of cases have been cured. 2. That in cases of inoperable cancer of the breast in women of about 40 years of age in whom the menopause has not occurred the operation of oöphorectomy should be proposed, and this treatment may be combined with thyroid feeding. 3. That in cases of inoperable rodent ulcer and in the superficial malignant ulceration in other parts the Roentgen rays give a good hope of improvement. 4. That in cases where these other methods are declined or are inapplicable the internal administration of celandine (chelidonium) is worthy of trial, and when the case appears quite hopeless morphia should be pushed without hesitation. 5. Finally, I would suggest that before trying any of these remedies the risk should be fully pointed out to the patient, that the faint hope that most of them afford should not be magnified, and that the discomfort of treatment should be fully discussed; in fact, the surgeon should not do more than offer the treatment and leave the person to accept or receive it."

Mucin in Desiccation, Irritation and Ulceration of Mucous Membranes. W. Stuart-Low.—The anatomy of the mucous coats and the physiology of their secretions are first noted by the author, who gives notes of his cases treated by the use of mucin. He uses tabloids containing 5 grains of mucin and sodium bicarbonate. The cases reported are those of irritable indigestion, which he ascribes to a desiccated condition of the mucous coats. He thinks that the substance acts by supplying the protective, indifferent non-peptonizable and hygroscopic substance, mucus, by administering it just before digestion begins. The sensitive ulcer or erosion or the inflamed wall is covered over or shielded from operation of the acid gastric juice and thus reflex secretion of the latter is prevented. One of the leading clinical indications for the administration of mucin tabloids, as prepared by Burroughs, Welcome & Co., is the presence of clean, red, angry, dry tongue, or a clean, red furrowed tongue, indicating the inefficiency of gastric or protective covering. If in association with this there is pain after feeding and constipation, it indicates not too much mucus in the stomach, as in catarrhal states, but really shortage of mucus; it is well to remove the old gastric mucus and prepare the way for mucin, to administer first a saline aperient. He carefully avoids peptonized foods or preparations in such cases as being unphysiological. For the first one-half hour and probably longer the acid gastric juice ought to be immediately neutralized as it is secreted by means of alkaline salts introduced in the food chiefly by uniting with the proteids of the meal; this is essential so that the amylolytic process may proceed. It is of supreme importance that such neutralization should take place in all irritable and ulcerative states unless the exposed and hypersensitive parts are to be worried by the free acid causing pain and inducing vomiting. Therefore, the administration of such prepared foods has been avoided. He finds that as soon as the patient can retain such a proteid as the essence of beef or fresh meat juice the pain becomes much less, and he relegates the use of such prepared foods to cases of worn-out stomach in the aged.

Cancer, Its Nature and Its Treatment. John Holden Webb.—The author gives in substance a similar article which has been noticed editorially in The Journal and which was first published in the *Australasian Medical Gazette;* the view was there stated that the malignancy is a riotous cell growth due to the lack of inhibiting substance provided by the liver. He regards it as a crystallization of cholesterin from the living cell. In carcinoma both tissue elements, cells and follicles, are represented so that the thyroid secretion is imperatively indicated, and he believes that the sole action of this body is to control proliferation of cells and that its action on metabolism is a snare and a delusion. His champion case is one of advanced cancer of the mouth in which the tongue, lower jaw, palate and tonsil had been removed, and where the action of the soap injections was most marked. The whole of the interior of the mouth and cheek when first seen was one mass of cancer. All smell and discharge are now gone and the patient has no pain. He does not expect recovery, but it is wonderful that he should get along as well as he does. He suggests certain precautions. No more than one teaspoonful of soap solution should be administered at one time. These injections are not absolutely without danger; another precaution is to never inject in one's office unless there is a bed for the patient to lie down for an hour or two afterwards. It is always well, he thinks, to employ anesthesia, nitrous oxid for instance. At first he injects nearly every day, and, with improvement, less frequently until one every week or ten days suffices. While he recommends a special soap, the common yellow bar soap will do. It should be dissolved in boiling distilled water and then drained through a sieve or closely woven calico to get rid of any particles of dirt.

Annales des Mal. des Org. Gen.-Urin. (Paris), August.

Special Points in Treatment of Prostatism. F. P. Guiard.—Among the points emphasized by Guiard are the benefits of small anodyne, rectal injections of antipyrin and laudanum in case of inflammation of the prostate. The most convenient method of making these injections is to insert a vaselined urethral catheter in the rectum, injecting the fluid through this catheter with a small glass syringe held in the lap. In order to prevent the formation of secondary calculi the sand accumulating should be aspirated once a month with a large metallic catheter. He also advocates a whalebone instead of a metal guide for urethral catheters, and the Trendelenburg position for lithotrity.

Bulletin de l'Academie de Med. (Paris), October 1.

Localization of Antimony in the Organism. G. Pouchet.—A recent criminal case of poisoning with antimony interested Pouchet in the subject, and he instituted a series of experiments on dogs and rabbits. The results seem to demonstrate that the toxic action of antimony is not manifested in comparison with arsenic, unless the dose is large, and that its localization is very different from the latter, while the combination of arsenic and antimony seems to enhance the toxic action of the former. Arsenic is refound in the brain, spinal cord, muscles and liver, but no antimony can be discovered in these organs. Traces of both metals are found in the bones, skin and hair, but the largest proportion of antimony is found in the alimentary canal, with a very small proportion of arsenic. The simultaneous administration of some other medicinal substance, such as potassium bromid, seems to modify to a remarkable extent both the symptoms and the localization of these poisons.

Revue Neurologique (Paris), September 15.

Effect of Sunstroke on the Brain. E. Regis.—The effect of a sunstroke is similar in many cases to that of an intoxication. The direct or indirect action of the heat or the autointoxication which it may induce, are liable to cause the symptoms of an acute or chronic intoxication. In a case described, the patient had acute delirium immediately after a second sunstroke. After three months the memory was defective and improvement was very slow and gradual, owing to mental and physical torpor which persisted even a year later. Hypnotic treatment was refused.

Semaine Medicale (Paris), October 2.

Abnormal Position of the Intestines. F. de Quervain.—The intestines may be generally in a normal position with a certain portion more or less irregularly situated, or the entire large intestine may be behind, or to the left or right of its normal place. In a case personally observed, the entire large intestine was in the right half of the abdomen, the third case of the kind on record. Retroposition and sinistroposition with their intermediate degrees are probably due to arrested development, dating from the fifth week of fetal life. The other anomalies are probably the result of some abnormal torsion of the umbilical loop at this early stage. The abnormal position of the intestines may bring the appendix into the small pelvis, on a level with the iliac crest, over the right kidney, or near the margin of the liver, and perforation may occur at any of these points. The inflammation of the appendix at these abnormal points may be mistaken for an affection of the gall-bladder, but mistakes of this kind would be avoided if the course of the cecum were more carefully traced. The transverse colon may extend upward and completely mask the liver dulness. Manteuffel has collected 24 cases, including 4 personally observed, of torsion of the cecum in which the tumor was not in the ileocecal region. Of this number 13 patients who were not operated on and 2 with an artificial anus, all died, but 6 recovered out of the 9 treated by laparotomy. In case of torsion of an abnormal sigmoid flexure the loop is generally voluminous and fills the larger portion of the abdominal cavity, either toward the left or right. Both the small and large intestine may become twisted around a common mesentery. The symptoms commence very abruptly in these cases, and collapse is so rapid that surgical intervention has hitherto failed to prevent the fatal termination.

Berliner Klin. Wochenschrift, September 16.

Soluble Silver as an Internal Antiseptic. Crede.—Soluble colloid silver is not an ideal solution, Credé admits, but no particles of silver are visible and it filters through blotting paper. It is tasteless, odorless and absolutely unirritating, while it proves extremely bactericidal even for very virulent staphylococci, as a destructive silver salt is formed from it by the action of the bacteria. Credé does not claim the priority of its invention, as he states that an American chemist exhibited argentum colloidale long ago as a scientific curiosity. He reports that three years of experience have confirmed his previous assertions in regard to its efficacy for external application, and its great value in country practice where asepsis is difficult. He is convinced that mercury and iodoform are responsible for many chronic, insidious, unrecognized intoxications, while silver is absolutely harmless. He recommends it now as a means of general internal disinfection in all streptococcus and staphylococcus infections not too far advanced. Abscesses and necrosis are, of course, not influenced by the silver, but phlegmons and all septic processes, epidemic cerebrospinal meningitis and erysipelas are favorably influenced. It has no action in subcutaneous injections and very little by the mouth. It must, therefore, be used in inunctions or by intravenous injection. He uses a 15 per cent. salve of the colloid silver, rubbing two or three grams into the skin after preliminary scrubbing and friction to induce hyperemia, and final rinsing with ether. When the skin is anemic, leathery, painful or incapable of absorption from any cause, intravenous injections take the place of the inunctions, from 5 to 20 c.c. of a .5 to 1 per cent. solution, repeating in one to eight days as required. He has treated cases of sepsis, acute rheumatism, fulminating gangrene, typhoid fever, scarlet fever with septic complications and advanced stages of pulmonary tuberculosis with the silver in inunctions or intravenous injections. All were exceptionally severe cases, but the marked benefit derived from the silver was apparent in every instance. Experiments on horses and other animals showed that the silver settled first in the lungs and liver and then left these organs for the spleen, kidneys and walls of the intestines. After a few weeks not a trace of the silver could be discovered in the organism. As it thus passes through the body so rapidly, its bactericidal effect is transient and the inunction has to be repeated three or four times a day and the intravenous injections twice, in order to obtain the maximal effect. Uncomplicated scarlet fever was not influenced by the silver. In case of infectious gastro-intestinal affections, he gives the colloid silver in pills or adds a teaspoonful to milk, cocoa or any albuminoid food three to six times a day.

September 23.

Prophylaxis of Tuberculosis and Isolation of Consumptives. B. Fraenkel.—In order to prevent infection of others, Fraenkel has long advocated that consumptives should wear masks to catch the droplets expelled in speaking or coughing. He now concedes that the prejudice against such a measure as the constant wearing of a mask is practically insuperable, and yet healthy guinea-pigs placed in a model tuberculosis ward where every precaution against the dissemination of the infection—except masks—was scrupulously observed, the sputa immediately destroyed, etc., nearly all succumbed to tuberculosis in a short time. He cites other arguments to prove that the only means of effective prophylaxis against the spread of "the white plague," is the isolation of all persons affected with it. He estimates that each consumptive infects at least one other person during the course of his disease, and that if the sickness-insurance companies once realize this, they will find it to their interest and advantage to take measures to isolate their consumptive policy-holders. The law now allows them the privilege of supporting their proteges in an institution instead of paying a cash indemnity, and the Berliner Versicherungsanstalt has already commenced the construction of an establishment of this kind for lung diseases too far advanced for admission to a sanitarium. The immense number of these incurables is the chief obstacle to their effective isolation, but if it could once be definitely accomplished the number would grow progressively less after the first few years, instead of the ever-widening circles of infection which now prevail. He does not advocate compulsory isolation, but thinks that consumptives would be glad to take advantage of a home in some dust-free, attractively situated house or barracks with hospital accommodations for the bedridden, in place of the present dreary surroundings of the consumptive poor. He relates several instances showing the inevitable spread of infection from such a source, among them the case of a consumptive dismissed from the public hospital and refused admission to any sanitarium, living with her family in a basement communicating with a thronged tavern.

Inhalations of Oxygen. E. Aron.—After extensive study of the action of inhalation of oxygen as a therapeutic measure, Aron announces his conviction that it is comparatively useless except in carbon dioxid or anilin intoxication, or in disturbances due to rarefaction of air.

Mechanical Reduction of the Hump in Pott's Disease. J. Joseph.—The examination of an anatomic specimen and radiography of a clinical case have established the fact, Joseph announces, that it is possible to reduce the hump and ensure permanent correction. But the mechanism is different from what is generally assumed. The entire spine becomes shorter, the weight above pushes down the diseased portion which settles down in a vertical position, and enough new bone tissue and adhesions form to maintain the spine in its vertical position. He applies a cast and corset which ensure continuous mechanical pressure on the hump, combined with extension, thus favoring the production of adhesions and new bone tissue that

are able to support the spine in its normal position and amply suffice to compensate the defect after the spine has settled down under the weight above.

Deutsche Med. Wochenschrift, October 10.

The Portal of Entry for Tubercle Bacilli and Their Localization in Man. P. GRAWITZ.—The histological difference between the tubercles in human and in bovine tuberculosis might be explained by the racial differences in the reaction of the tissues. For example, the literature on actinomycosis shows that these microbes cause suppuration in man, while in animals they induce the formation of a tumor. Only one case is on record of an actinomycotic tumor in a human brain. Besides this racial predisposition to a given kind of reaction, there is an individual predisposition which varies with the age, food and manner of life. An example of this varying individual reaction is afforded by Busse's experiments on rats. Inoculated with a certain fungus derived from man, none of the animals showed any signs of infection until the females littered and nursed their young. At this time they commenced to grow thin and numerous foci were found in them, while the male animals remained healthy. The puerperium, measles, influenza, typhoid fever and diabetes frequently cause a temporary predisposition to tuberculosis. The debilitated tissues are unable to resist the encroachments of the bacilli and to throw up a wall of granulations around them. A slight injury of the finger in a diabetic may lead to extensive gangrene instead of mere suppuration with a demarcation of granulations as in a healthy subject. In anemic, debilitated children, some slight injury of the mouth or lip may allow the bacteria or cocci to enter, and as they proliferate in the tissues, their ptomains may induce local necrosis or noma to which the tissues oppose no obstacle. The influence of this individual permanent or temporary predisposition is so decisive that Grawitz considers it idle to dream of the final extinction of tuberculosis by the gradual extermination of the bacilli. The predisposition is the main disease, as, for instance, in the case of a diabetic, the diabetes. The tuberculosis is the accident, the same as the carbuncle or symmetrical gangrene in the latter case. Besides the racial and the individual predisposition, there is a predisposition of the organs. Grawitz and Menne have observed forty-two cases of tuberculosis of the internal genitalia in virgins. In a certain number of the cases infection probably occurred from the peritoneum, but in a large proportion, it was explainable only by transmission of infection by way of the blood or lymph. There was no anatomic difference between the lesions by these routes. The epididymis, the apices of the lungs, etc., are favorite nesting-places for the bacilli arriving by way of the blood, and the infrequency of tubercular lesions of the larynx and trachea seems to indicate that tuberculosis of the air passages is not necessarily always due to the inhalation of germs. The frequency of tuberculosis of the intestines has been accepted as proof that the germs must have been ingested in the food. But the rarity of cases in which the intestines alone are infected, shows that only a very small percentage can properly be attributed to this source. Intestinal tuberculosis is accompanied by pulmonary lesions far more frequently than tubercular joint affections or spondylitis. Consequently it appears that only an extremely small proportion of the fatal cases of tuberculosis can be ascribed to infection by way of the food, and when the cases of infection from diseased meat or the swallowing of germs from the air, are subtracted from the total number, scarcely any cases are left that can be attributed to the ingestion of milk from tuberculous cows. More than 25 per cent. of the last series of cadavers at the Griefswald pathological institute, exhibited evidences of tubercular infection at some time. Of the total number, only three children and one man had tubercles in the intestines or mesenteric tabes, without some focus in the lung whence they could have been derived. The intestinal mucosa is not a favorite point for the bacilli to settle. It often remains intact even when the mesenteric glands are severely infected and when for years sputa abounding in bacilli have been habitually swallowed. On the other hand, the bacilli seem to have a special predilection for the tonsils. Old caseous foci and fresh tubercles with giant cells and bacilli, are frequently encountered in the tonsils even when they are small and present a normal external aspect. From the tonsils, the bacilli can pass easily into the cervical lymphatic glands, and even in the absence of any apparent tumefaction of the glands, the bacilli can travel on to the hilus of the lung and thence invade the lung, pleura or pericardium. The child may die in consequence, without exhibiting the slightest indication in the intestines or mesenteric glands that the food was in reality the bearer of the primary infection. It is difficult to prove that the tubercle bacilli entered the follicles of the tonsils from the food, but the assumption is as plausible as for the caseous foci and tubercles in the lymph follicles of the intestines or mesenteric tabes. Further research in this line is necessary, especially to determine the order in which the organs are affected, with microscopic investigation of the tonsils in case of chronic, suspicious swelling of the cervical glands. The autopsy in the rare cases of pure tuberculosis of the intestines may afford evidence that the tubercle bacilli were swallowed in the food, but negative findings in case of general tuberculosis by no means exclude this possibility, even when the entire intestines and their lymphatic apparatus are found intact. The entire number of the *Wochenschrift* is devoted to Virchow, and this communication from Grawitz is also dedicated to "the great skeptic in pathology."

Proliferation of Neuroglia. V. BABES.—The latest research has only confirmed Virchow's assertions in regard to the nature of the neuroglia. They have been characterized as the divination of genius, as no previous research or work by others had led up to his conception of the neuroglia. The details of the finer structure, the fibers and the relations between the neuroglia, the vessels and the nerve elements, and its nutritional and secretory activity, have been later discoveries, but all sustain and supplement his early research.

Analysis of the Feces. H. URY.—Thorough extraction with water of fresh fecal matters from a healthy subject, allows the essential intestinal secretions to be preserved in the aqueous extract, while the remains of the food filter out as insoluble detritus. This method of procedure is not absolutely exact as it takes no account of the epithelium shed by the intestinal walls. But the quantity of this epithelial substance is very small in health and can be disregarded in practice. Among the interesting points learned by this method we note that Ury found that in typhoid fever, notwithstanding the copious diuresis, most of the alkaline salts are eliminated by the intestinal walls instead of by the kidneys as in normal conditions. He found also that an average of 1.6244 gm. of nitrogen was eliminated in the feces in twenty-four hours, on a mixed diet, of which .39 gm. passed into the aqueous extract. To determine the proportion of lime, he evaporated the filtrate over the water-bath, reduced the residuum to ashes and determined the lime in the latter. The quantity was always minimal and most of it was evidently derived from the food. About 26.2 per cent. of the total phosphorus in the feces passed into the aqueous extract; 89.6 per cent. of the combined phosphorus was eliminated in the urine and 10.1 per cent. in the aqueous extract. These latter proportions were so constant that they indicate a physiologic law.

Monatshefte f. Prakt. Dermatologie (Hamburg), July 1.

Treatment of Epididymitis. M. POROSZ.—Experiments on dogs have shown that the disturbances in the circulation in the epididymis are frequently of reflex origin. The organ, not the patient, requires rest. Hot applications should be scrupulously avoided as they increase the inflammation. Porosz recommends injections of a weak solution of subacetate of lead, and the application of a Falkson suspensory after anointing the scrotum with vaselin.

July 15.

Elective Double Stain for Plasma Cells. A. PAPPENHEIM.—If resorcin is added to the methyl green and pyronin stain, the latter is fixed by the substances to which it has a chemical affinity and washes out of the rest of the specimen.

The resorcin is applied in an alcoholic solution after staining for five minutes. This stains the specimen in four colors.

August 15.

Etiology of Eczema. E. BENDA.—In extensive experimental tests, inoculation of staphylococci, isolated or in cultures, invariably produced impetigo, while inoculation of the staphylococcus toxins, both with and without the cocci themselves, invariably induced eczema.

Monatschrift f. Ohrenheilkunde (Berlin), August.

Diagnostic Significance of Rhodan Reaction in Saliva in Case of Otitis. E. JUERGENS.—The saliva from the parotid gland normally contains considerable rhodan, but in case of disturbance in the innervation, accompanying an affection of the middle ear, tests for rhodan are negative. The rhodan test is, therefore, important for the diagnosis of an existing suppuration of the middle ear or other aural affection, although the test is less reliable in smokers.

Muenchener Med. Wochenschrift, October 1.

Significance of Elastic Fibers in Pathologic and Regenerative Processes. B. GROHE.—After a historical review of the various theories in regard to the significance of the elastic fibers, Grohe describes his experimental research on the subject. He fractured the radius or ulna in young rabbits, leaving the other bone as a natural splint. The elastic fibers were ruptured in the fracture and the young regenerated fibers penetrated the external callus and also the inner marrow callus. They usually develop where there is most need for solidity and a fastening of the parts. He found that the new fibers almost invariably proceed from the old, and remain in connection with them. In the bone marrow the only elements containing elastic fibers are the delicate vessels, and the regenerated fibers probably therefore proceed from the elastic fibers in the vessels.

A Case of Tumor-Like Hyperostosis of the Skull. A. SCHILLER.—About sixteen cases of diffuse hyperostosis of the skull have been published, but not more than a dozen cases of the tumor-like hyperostosis. In the case described, the ostosis had never caused brain trouble, and the fact that the excessive bone development ceased with the general growth, as well as its anatomic location, suggested that it was merely an excessive functioning of the physiologic centers of ossification of the skull. The prognosis in this case is probably favorable, although there is always a possibility that trauma or inflammatory fluxion, etc., may arouse the latent disposition to excessive bone-formation and induce further proliferation.

The Diplococcus Semilunaris as the Companion of Tuberculosis. E. KLEBS.—The frequent association of the semilunar diplococcus with the tubercle bacillus explains, perhaps, the inefficacy of specific treatment directed against the latter. It frequently flourishes after the tubercle bacillus has finished its career, especially in tubercular joint and bone affections. When these diplococci are numerous, the prognosis is less favorable as the fact indicates lesser resisting power on the part of the tissues. In experiments on animals the diplococcus induced atrophy of the various organs, especially of the blood-producing, or phlegmonous inflammation. This power of the diplococcus to induce atrophy is very serious in a debilitated tuberculous subject, and may entail phthisis even when the tuberculous processes are almost entirely cured. The emaciation of an old self-immunized phthisic may possibly be due to this mixed infection with the semilunar diplococcus.

A Case of Pseudo-Leukemia and Glycosuria. A. GOLDSCHMIDT.—The protracted course of this case of pseudo-leukemia was probably due to the nourishing food and care and rest which the patient was able to procure. An intermittent glycosuria was a prominent feature of the case, accompanied by occasional irregular fever. The glycosuria was not influenced by the food and toward the last vanished completely. Lactophenin seemed to be the most effective remedy to control the fever and nervous disturbances. Arsenic was not tolerated by the patient after the first.

October 8.

Transfusion of Saline Solution in Experimental Tetanus. C. TONZIG.—Moschowitz has recently published statistics which demonstrate that the mortality of tetanus has fallen from 90 to 40 per cent. since the introduction of antitetanus serum, and that Tizzoni's is proving the most effective. Bacelli's method of subcutaneous injection of an aqueous solution of carbolic acid is not fulfilling the anticipations it first aroused. Saline transfusion has proved successful in the experience of some physicians and theoretically is indicated in tetanus. Gomez reports the cure of a severe case in a boy of 7 by subcutaneous injection of 250 gm. a day of a .75 per cent. saline solution. Lasletta has found saline transfusion extremely effective in diphtheria at a time when antitoxin treatment had lost its efficacy. Others have reported fine results from rectal injections of saline solution in typhoid fever and tetanus, with or without supplementary drawing of blood by leeches. Tonzig reports the results of ten series of experiments on large numbers of rabbits. The results failed to demonstrate any absolutely favorable action from saline solution injected into the peritoneum. The tests proved that the tetanus toxin does not circulate in the blood, but evidently fastens on the cells. This lavage of the organism, however, postponed the fatal termination for several days, when the onset of the infection was not particularly stormy. It, therefore, has a certain value which should not be forgotten when for any cause antitoxin treatment is not practicable.

Statistics in Regard to the Diminishing Mortality from Tuberculosis. A. GOTTSTEIN.—By comparing the tabulated statistics of twenty-three Prussian cities, Gottstein finds that the mortality from tuberculosis has been steadily diminishing since 1876 so far as adults are concerned, but that in individuals under 20, the mortality remained high until 1894, when it began to diminish a little. This difference in the curves of tuberculosis in children and in adults is probably due to the different localization of the disease. The mortality is influenced by the progress in surgery, which has reduced the mortality in children from surgical tuberculosis. Since 1894 the infant mortality has been reduced to four-fifths of what it was in 1881, which is probably due to the improvement effected in the milk supply about that time.

Gazzetta Degli Ospedali (Milan), October 6.

Bubonic Plague. LUCATELLO.—The recent small outbreak of plague at Naples is the occasion of this historical and clinical review of the subject. Lucatello states that the antiplague serum made by Lustig at Florence has reduced the mortality to 46.15 per cent. in the cases in which it has been used, and that it has been tried on an extensive scale at Bombay.

Two Cases of Osteomalacia Treated by Castration. S. CATELLANI.—One patient, a woman of 29, was completely cured by the castration; the other was 39 years old, and the operation relieved her of all pain, but did not prevent a fatal termination seven months later. In the latter case a remarkable remission in the symptoms had been observed in the course of the disease, coinciding with suspension of the menses for six months. When menstruation returned, the osteomalacia resumed its progressive course. The pains permanently disappear in the first or second day after castration. The prolonged administration of phosphorus has cured certain patients and Morpurgo has succeeded in inducing in animals the production of localized alterations in the bones resembling those of human osteomalacia, by microbian lesions in the spine. These facts all tend to establish the close connection between the genital organs and nervous system and the osteomalacic processes.

Nordiskt Med. Arkiv (Stockholm), 1901, i, 2.

Primary Tuberculosis of the Intestines. V. GRIMSGAARD.—In the case described, the cachexia was caused by autointoxication and by the fatty degeneration of heart and liver, which induced edema, commencing nine months after the first signs of the intestinal trouble. The symptoms had been attributed to a gastric affection until the edema appeared, when the pain assumed more and more the character of colic pains and König's stricture syndrome was presented. The patient

was a married woman of 59, hitherto healthy. Operation was refused on account of the bilateral ascites and edema and the pronounced cachexia, although the patient was not emaciated. On her insistence, an ileo-colostomy was done, to exclude the portion of the small intestine containing the multiple strictures, but the heart was too much degenerated to allow her to rally from the operation. In the 114 cases of tuberculosis of the cecum which have been published, the symptoms indicating a stricture had persisted from six to twelve months in 15; from one to two years in 14; from two to three years in 20 and in one for nine years, for twelve in another, for several years in 3, and for four to eight years in 15. In the 69 cases in which these details are given, 60 per cent. of the patients were between 30 and 40, and only 7 were over 50 and one over 59. The age seems to have a certain influence on the course of the disease. In the first place, chronic nutritional disturbances are more liable to induce fatty degeneration of the heart in elderly than in young persons. Secondly, the characteristic symptoms of a stricture require a longer time for their gradual evolution in elderly persons. In all the case reports it is apparent that the attacks were infrequent at first, with long intervals between them, and that the disease was not recognized until they became more frequent. By this time the stricture is very narrow and compensatory hypertrophy has developed, but the nutritional disturbances and the resulting autointoxication have long been at work, months or years before the pains become violent. When the hypertrophy above the stricture is insignificant, meteorism may exist without the characteristic attacks of pain which are the result of the violent peristalsis of the central portion of the intestine. In the personal case reported, the attacks of colic in 1895 probably had been the first symptoms of the stricture which did not exhibit the unmistakable characteristic picture until five years later, when intervention was too late. The patient's age probably was the reason of the slow development of the compensating hypertrophy.

Simultaneous Extrauterine and Intrauterine Pregnancy. H. CHRISTER-NILSSON.—Pains in the abdomen, occasional scanty hemorrhage from the uterus and evening vomiting, were the only symptoms, but palpation disclosed a tumor on the right Fallopian tube and that the uterus was increasing in size. The patient was a healthy iii-para. A simultaneous extrauterine and intrauterine pregnancy was diagnosed and the tube and ovary were removed without disturbing the uterus. The patient rapidly recovered, but six weeks later the uterine pregnancy was terminated by an abortion following a severe fright. Sixty-seven cases of these simultaneous pregnancies in and outside of the uterus have been published. In Sale's case the laparotomy was done when both fetuses were at term and viable. The "ectoper" was extracted first, and then the normal fetus by Cesarean section. The mother died four days later, probably of sepsis. Only the extrauterine pregnancy had been diagnosed in this case. In Franklin's case, the normal fetus was extracted by Cesarean section and a dead fetus from Douglas' pouch. The mother died of hemorrhage from the ectopic placenta. Besides Sale, Wilson and Chrobak each delivered a viable "ectoper." Ten patients treated expectantly recovered. The fetus left in the abdomen was fully developed in some of these cases. Nineteen other cases of expectant treatment out of a total of 38, terminated fatally. Whitcomb treated a case by killing both of the fetuses at the third month by electricity. They were expelled later by the uterus and the mother recovered. All the patients recovered who came under treatment after the intrauterine pregnancy had been interrupted, with one exception. In Mathewson's case, according to the abstract in the *Cbl. f. Gyn.*, 1898, p. 1421, the fully developed extrauterine fetus was killed with a stiletto after successful delivery. In nine cases in which the pregnancy had lasted less than four months, the entire pregnant tube was ablated with recovery in all but one case. About 80 per cent. of the women had passed through one or more previous pregnancies in the 52 cases in which this detail was mentioned. In one patient it was the eighth pregnancy, in another the twelfth and in another the nineteenth. In only one of all the cases reported was the pregnancy confined to the ovary. The right tube is usually involved, but in three cases the ectopic pregnancy was interstitial.

1901, ii, 2.

Tuberculous Strictures of the Small Intestine. J. FIBIGER.—In two cases described in detail, the discovery of multiple strictures in the small intestines was an autopsy surprise. No symptoms had been recognized during life, and the lesions were almost completely healed. There were progressing tubercular lesions in the lungs. In one case the patient had passed through a supposed abdominal typhoid fever twenty-one years before, and for a few years afterward a tendency to diarrhea or constipation had been noted. Fibiger thinks that these symptoms were probably the manifestations of the tuberculous process at its height. In the other case, no symptoms of any kind had ever attracted attention to the intestines. Neither of the patients showed signs of anemia. The healing process had been so complete that all the characteristic alterations of the tissues and the bacilli had vanished except in a very few of the 342 sections of the intestines that had been mounted, which still showed signs of the tuberculous ulceration in the stricture. Repeated microscopic examination of the mesenteric glands was also necessary before the tuberculous nature of the adenitis could be established. Reach has collected 91 cases of multiple strictures of the intestines, and found that tuberculosis was the cause in 42, carcinoma in 6, syphilis in 12, dysentery in 1, typhoid fever in 1, and no cause could be assigned in 17. Fibiger is convinced that these multiple strictures have been sometimes erroneously attributed to syphilis in the past. He describes two typical cases, in which the proliferating, obliterating endophlebitis in the veins of the mesentery and the aspect of the strictures suggested a syphilitic origin, but extremely careful microscopic examination of the tissues established their tuberculous nature. He thinks we have no right to exclude a tuberculous origin, unless we obtain negative results from the combined microscopic investigation of the strictures and of the glands of the mesentery and liver. On the other hand, a syphilitic origin is evident in the few published cases of affections of the small intestine consisting in a fibrous, shrivelling process and tumor-like infiltrations on the intestinal wall, unmistakable cicatricial formations in gummatous nodules. The frequency of these tuberculous strictures in the intestine seems to be increasing, as Fibiger has observed seven cases in the last two years. As the tuberculous lesion heals, cicatricial stenosis follows and the healing generally accompanies a remission in the pulmonary process which, he remarks, almost inevitably coexists with the intestinal affection. As the pulmonary lesions heal, the general health improves and the constant irritation from swallowed sputa is abolished. If it is a fact that the frequency of these cicatricial stenoses is increasing, this may be explained by the greater prevalence of benign, fibrous forms of pulmonary tuberculosis, which Lange has noted for Copenhagen at least. Conrath has suggested that the tubercle bacilli derived from the food are different from the ordinary human bacilli and that the primary chronic hypertrophic tuberculosis of the cecum may be a different kind of a tuberculous lesion.

Bacteriology of Cerebrospinal Meningitis. I. JUNDELL.—In 387 cases of acute, primary meningitis, epidemic and sporadic, pure cultures of the meningococcus were derived in 249 cases, and of the pneumococcus in 106. In only 32 cases, or 8.3 per cent., were different results obtained.

Malignant Disease in Norway. M. GEIRSVOLD.—The statistics that have been collected in Norway since 1878 show that cancerous affections are increasing in frequency, and that certain localities seem to be peculiarly prone to cancer. It is more frequent in the cities. The occupation and station in life seem to have no influence whatever on the dissemination of cancer unless it reduces the average length of life below 60, the cancer-breeding age. In 79.6 per cent. of the 15,555 cases in which the location is specified, the cancer occurred in the alimentary canal, including about 4 per cent. in the mouth or

throat. This fact inevitably suggests some connection between the food and the development of cancer.

Oliguria. N. VEDELER.—Five elderly women have been treated by Vedeler for scantiness of urine. The trouble simulated a cystitis at first; the concentrated urine, the abundance of sediment and pains during and after micturition. But the absence of bacteria and pus from the urine and the rapid response to treatment showed that the affection was exclusively nervous, an actual decrease in the secretion. One patient was treated with Faradization of the kidney region, another with asafetida. There were no indications of retention nor of hysteria at any time.

Necessity for Small, Numerous Sanitariums for Tuberculous Subjects. M. HOLMBOE.—Besides the large sanatoria, Holmboe pleads for a small establishment in every community, where tuberculous subjects can be treated near home. For most of them four to six beds would be sufficient, and when more than twenty are required, another of these temporary homes should be equipped.

Respiratory Exercises in Pulmonary Tuberculosis. C. F. LARSEN.—Modern sanatorium treatment does not pay sufficient attention to the exercise which tuberculous patients require. The influence of the air on the lungs could be multiplied by systematic exercises in breathing, expelling the residual air by vigorous expiration. Inspiration can not be forced without danger, perhaps, but expiration should be vigorous. The best of all measures is to increase the respiration in general by systematic walks instead of so much reclining. Both circulation and respiration are stimulated by suitable exercise of this kind, graduated to each case.

Chorea and Rheumatism. S. LAACHE.—During the last seventeen years Laache has had occasion to observe 390 cases of acute rheumatism, and has traced them to date, but has been unable to discover a single case in which chorea appeared. He is inclined to define chorea as a "growth neurosis," an anomaly in development, although he admits an endocardo-rheumatic, infectious variety and a neurasthenic. Four of his forty patients with chorea died. In two the autopsy disclosed fatty degeneration of the kidneys, and in two endocarditis. He attributes great importance to fright, as a determining cause. School chorea is due to anemia and chlorosis fully as much as to mental strain. Pains in the joints were noticed in 18 per cent. A heart affection was evident in 42 per cent., but it was slight in all but 18 per cent. He considers arsenic the chief reliance in treatment, administered by the mouth or in the form of subcutaneous cacodylic injections. He has found potassium bromid the best and most harmless narcotic. (Originally published in the *Norsk. Mag. f. Lägevid.*, 1900, p. 97.)

Queries and Minor Notes.

INDIANA MEDICAL PRACTICE ACT.

TOLEDO, ILL., Oct. 18, 1901.

To the Editor:—To obtain a license from the Indiana State Board, is a graduate of the Medical College of Ohio, U. C., holding a certificate issued by Illinois State Board, required to pass an examination? If so, when and where will the next one be held?

B. C. R.

ANS.—Yes. The next regular meeting is to be held in Indianapolis, the second Tuesday in January.

OREGON AND WASHINGTON B. OF H. SECRETARIES.

CHICAGO, Oct. 23, 1901.

To the Editor:—Would you kindly state in the next issue of THE JOURNAL who the secretaries of the Boards of Health are of Washington and Oregon, and where they are located? A. H. G.

ANS.—Dr. Byron E. Miller, Portland, Ore.; Dr. J. P. Turney, Davenport, Wash.

New Patents.

683,589. Insufflator. Wm. F. Barry, Woonsocket, R. I.
683,680. Electro-massage device. Lee J. Chapman, Columbus, Ohio.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A CIVILIAN WAR HOSPITAL. Being an Account of the Work of the Portland Hospital, and of Experience of Wounds and Sickness in South Africa, 1900. With a Description of the Equipment, Cost and Management of a Civilian Base Hospital in Time of War. By the Professional Staff, Anthony A. Bowlby, C.M.G., F.R.C.S., Senior Surgeon; Howard H. Tooth, M.D., C.M.G., F.R.C.P.; Cuthbert Wallace, M.B., B.S., F.R.C.S.; John E. Calverley, M.B., B.S., M.R.C.S.; and Surgeon-Major Kilkelly, C.M.G., Grenadier Guards, Principal Medical Officer and in Military Charge. With Numerous Illustrations. Cloth. Pp. 341. Price, $4.00. New York: Longmans, Green & Co. 1901.

A TEXT-BOOK OF SURGERY. By Dr. Hermann Tillmans, Professor in the University of Leipsic. Translated from the Seventh German Edition by Benjamin T. Tilton, M.D., Instructor in Surgery, Cornell University, and John Rogers, M.D., Instructor in Surgery, Cornell University. Edited by Lewis A. Stimson, M.D., Professor of Surgery, Cornell University. Volume I. The Principles of Surgery and Surgical Pathology. With 516 Illustrations. Cloth. Pp. 841. Price, $5.00 per volume. New York: D. Appleton & Co. 1901.

MATERIA MEDICA, PHARMACY, PHARMACOLOGY AND THERAPEUTICS. By W. Hale White, M.D., F.R.C.P., Physician to and Lecturer on Medicine at Guy's Hospital, London. Edited by Reynold W. Wilcox, M.A., M.D., LL.D., Professor of Medicine and Therapeutics at the New York Post-Graduate Medical School. Fifth American Edition, Thoroughly Revised. Cloth. Pp. 744. Price, $3.00. Philadelphia: P. Blakiston's Son & Co. 1901.

THE PRINCIPLES AND PRACTICE OF MEDICINE. Designed for the Use of Practitioners and Students of Medicine. By William Osler, M.D., Fellow of the Royal Society. Fourth Edition. Cloth. Pp. 1182. Price, $5.50. New York: D. Appleton & Co. 1901.

A TREATISE ON MEDICAL JURISPRUDENCE. Based on Lectures Delivered at University College, London. By George Vivian Poore, M.D. (Lond.), F.R.C.P., Professor of the Principles and Practice of Medicine, University College, London. With Illustrations. Cloth. Pp. 533. Price, $4.00. New York: Longmans, Green & Co. 1901.

DISEASES OF THE UPPER RESPIRATORY TRACT, the Nose, Pharynx and Larynx. By P. Watson Williams, M.D. Lond., Physician in Charge of the Throat Department at the Bristol Royal Infirmary. Fourth Edition. Illustrated. Cloth. Pp. 436. Price, $6.00. London: Longmans, Green & Co. 1901.

THE TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA. Thirty-first Annual Session, Sacramento, April, 1901. Vol. XXXI. Cloth. Pp. 419. Published by the Society.

REPORT OF THE COMMISSIONER OF EDUCATION for the Year 1899-1900. Volume I. Cloth. Pp. 1280. Washington: Government Printing Office. 1901.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., October 10 to 16, 1901, inclusive:

Arthur I. Boyer, contract surgeon, on being relieved from duty at Fort Lawton, Wash., will proceed to New York City, for annulment of contract.

William J. Calvert, lieutenant and asst.-surgeon, U. S. A., from the General Hospital, Washington Barracks, D. C., to Fort McHenry, Md., for post duty.

Clyde S. Ford, lieutenant and asst.-surgeon, U. S. A., leave of absence granted.

Robert J. Gibson, major and surgeon, U. S. A., on being relieved from duty at San Francisco, Cal. (see Ogden Rafferty below), will report for transportation to Manila, P. I., and subsequent assignment in the Division of the Philippines.

Evan P. Howell, lieutenant and asst.-surgeon, U. S. A., from Fort Duchesne, Utah, to duty at Fort Clark, Tex.

Frank R. Keefer, captain and asst.-surgeon, U. S. A., on being relieved by Captain Reynolds (see below), to rejoin his station at Fort Monroe, Va.

Henry S. Kierstedt, lieutenant and asst.-surgeon, U. S. A., now on duty in the field with Troop H, 5th Cavalry, is relieved from duty in the Division of the Philippines, and from temporary duty in the Department of California; on his return to the Presidio of San Francisco, Cal., from field duty he will proceed to Fort Lawton, Wash., to relieve Contract-Surgeon Arthur J. Boyer.

Louis A. La Garde, major and surgeon, U. S. A., detailed as lecturer on the results of gunshot injuries at the Army Medical School, Washington, D. C.

Ogden Rafferty, captain and asst.-surgeon, U. S. A., relieved from further duty in the Division of the Philippines, and will proceed to San Francisco, Cal., for duty as attending surgeon and medical superintendent of the Army Transport Service, relieving Major Robert J. Gibson, surgeon, U. S. A.

Henry I. Raymond, major and surgeon, U. S. A., on being relieved from duty in Chicago, Ill., will proceed to San Francisco, Cal., en route for assignment in the Division of the Philippines.

Thomas W. Raymond, major and surgeon, U. S. Vols. (captain and asst.-surgeon, U. S. A.), relieved from further duty in the Division of the Philippines, and will proceed to Chicago, Ill., for duty as attending surgeon and examiner of recruits.

Frederick P. Reynolds, captain and asst.-surgeon, U. S. A., is detailed a member of the board in Washington, D. C., to examine candidates for admission into the Medical Corps of the Army, to take effect Oct. 31, 1901, relieving Captain Frank R. Keefer, asst.-surgeon, U. S. A.

Lewis A. Thompson, contract surgeon, leave of absence extended on account of sickness.

Hobart E. Warren, contract surgeon, now on duty at Denver, Colo., will proceed to the General Hospital, Fort Bayard, N. M., for duty at that hospital.

M. Manley Waterhouse, contract surgeon, is relieved from further duty on the transport *Logan*, and from temporary duty at the General Hospital, Presidio of San Francisco, Cal., and will proceed to Fort Wadsworth, N. Y., for duty.

Samuel M. Waterhouse, lieutenant and asst.-surgeon, U. S. A., from Fort Meade, S. D., to San Francisco, Cal., en route to Manila, P. I., for assignment in the Division of the Philippines.

Charles E. Woodruff, major and surgeon, U. S. A., from Fort Riley, Kan., to San Francisco, Cal., en route to Manila, P. I., for assignment in the Division of the Philippines.

In addition to the above, the following order was published on Oct. 12, 1901:

By direction of the Acting Secretary of War, the following-named assistant surgeons, U. S. A., are relieved from temporary duty at the posts designated after their respective names, and will report in person, on Nov. 1, 1901, at the Army Medical Museum Building in Washington, D. C., to Colonel William H. Forwood, assistant surgeon-general, U. S. A., president of the faculty of the Army Medical School, for the course of instruction prescribed in paragraphs 542 and 543, Army Regulations, 1901: All are first lieutenants and asst.-surgeons, U. S. A.:

Jerome S. Chaffee, Columbus Barracks, Ohio.
Charles C. Greer, Fort McPherson, Ga.
Ernest L. Ruffner, Columbus Barracks, Ohio.
Eugene R. Whitmore, Fort Sheridan, Ill.
Conrad E. Koerper, Washington Barracks, D. C.
Robert U. Patterson, Fort McHenry, Md.
Roderick F. O'Connor, Fort Myer, Va.
George P. Heard, Fort McPherson, Ga.
Roger Brooke, Jr., Fort Myer, Va.
Arthur M. Line, Fort Sheridan, Ill.
Verge E. Sweazey, Fort Columbus, N. Y.
Matthew A. DeLaney, Fort Monroe, Va.
Horace D. Bloomberg, Plattsburg Barracks, N. Y.
Paul S. Halloran, Fort Wadsworth, N. Y.
Kent Nelson, Washington Barracks, D. C.
Robert Smart, Fort Monroe, Va.
Lloyd LeR. Krebs, Fort Leavenworth, Kan.
William P. Woodall, Fort Clark, Texas.
Herbert M. Smith, Fort Monroe, Va.

Navy Changes.

Changes in the Medical Corps of the Navy, week ending Oct. 19, 1901:

Asst.-Surgeon F. M. Furlong, ordered to the Naval Hospital, New York, for treatment.

Pharmacist I. N. Hurd, detached from the Boston Navy Yard and ordered to the *Wabash*.

Surgeon S. H. Griffith, order to report for duty as a member of medical examining boards modified, ordered to report as a member of the medical examining board only, and not as a member of board for examination of medical officers.

Dr. H. R. Webb, commissioned asst.-surgeon from Oct. 11, 1901.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the twenty-one days ended Oct. 17, 1901.

Surgeon H. W. Austin, granted leave of absence for one month from October 7.

P. A. Surgeon A. R. Thomas, to proceed to Naples, Italy, and report to P. A. Surgeon J. M. Eager for duty.

Asst.-Surgeon W. C. Billings, relieved from duty at Los Angeles, Cal., and directed to proceed to Chicago, and report to the medical officer in command for duty and assignment to quarters.

Asst.-Surgeon C. W. Wille, granted leave of absence for seven days from October 17.

Asst.-Surgeon B. S. Warren, granted two days' extension of leave of absence.

A. A. Surgeon J. C. Rodman, granted leave of absence for four days.

A. A. Surgeon H. H. Stearns, granted leave of absence for fourteen days from October 10.

A. A. Surgeon R. T. Walker, granted leave of absence for three days.

Sanitary Inspector Lea Hume, granted leave of absence for October.

Surgeon C. E. Banks, granted leave of absence for four days from October 9.

Surgeon L. L. Williams, to proceed to Baltimore, Md., as inspector.

P. A. Surgeon C. P. Wertenbaker, three days' leave of absence from Oct. 5, 1901, under paragraph 179 of the regulations.

P. A. Surgeon C. H. Gardner, one day's leave of absence under paragraph 179 of the regulations.

Asst.-Surgeon M. H. Foster, granted leave of absence for four days.

A. A. Surgeon Felix Giralt, to proceed to Vera Cruz, Mexico, for temporary duty.

A. A. Surgeon Jay Tuttle, granted leave of absence for thirty days from October 4.

A. A. Surgeon W. S. Walkley, granted leave of absence for eleven days from September 28.

Hospital Steward S. W. Richardson, granted leave of absence for two days.

Hospital Steward H. Walerius, relieved from duty at Memphis, Tenn., and directed to proceed to Portland, Me., and report to the medical officer in command for duty and assignment to quarters, relieving Hospital Steward E. H. Holt.

Hospital Steward E. H. Holt, upon being relieved by Hospital Steward M. Walerius, to proceed to Memphis, Tenn., and report to medical officer in command for duty and assignment to quarters.

P. A. Surgeon J. A. Nydegger, upon being relieved by Asst.-Surgeon J. M. Holt, to proceed to Baltimore, Md., and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon J. M. Holt, upon arrival of Asst.-Surgeon W. C. Billings, to proceed to Cairo, Ill., relieving P. A. Surgeon J. A. Nydegger, and assume temporary command during absence of P. A. Surgeon J. H. Oakley on leave.

A. A. Surgeon D. E. Dudley, granted leave of absence, on account of sickness, for thirty days from October 7. Granted leave of absence for thirty days from November 7.

A. A. Surgeon B. W. Goldsborough, granted leave of absence for ten days from October 10.

Hospital Steward E. S. Maguire, granted leave of absence for seven days from October 6.

Hospital Steward W. F. Schlaar, granted leave of absence for thirty days from October 15.

Hospital Steward Frank Siedenburg, directed to report to medical officer in command, Chicago, for duty and assignment to quarters.

BOARD CONVENED.

Board convened for the purpose of selecting site for quarantine station at Brunswick, Ga. Detail for the Board: Surgeon J. H. White, M.-H. S., chairman; Captain J. C. Mitchell, R.C.S.; A. A. Surgeon Hugh Burford, M.-H. S., recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended October 19, 1901:

SMALLPOX—UNITED STATES.

Iowa: Ottumwa, Sept. 7-28, 24 cases.
Massachusetts: Boston, Oct. 5-12, 5 cases.
Michigan: Detroit, Oct. 5-12, 1 case.
New Jersey: Oct. 5-12, Camden, 1 case; Newark, 4 cases, 3 deaths.
New York: New York, Oct. 5-12, 7 cases, 2 deaths.
Ohio: Youngstown, Oct. 5-12, 1 case.
Pennsylvania: Oct. 5-12, Erie, 2 cases; Norristown, 1 case; Philadelphia, 60 cases, 2 deaths.
Rhode Island: Newport, Oct. 5-12, 1 case.
Vermont: Burlington, Sept. 28-Oct. 12, 13 cases.
Wisconsin: Green Bay, Oct. 6-13, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, Sept. 21-28, 4 cases.
Belgium: Sept. 21-28, Antwerp, 2 cases, 1 death; Ghent, 1 death.
Brazil: Rio de Janeiro, Aug. 18-Sept. 1, 115 deaths.
Colombia: Colon, Sept. 30-Oct. 6, 1 case; Panama, Sept. 30-Oct. 7, 125 cases.
Ecuador: Guayaquil, Aug. 3-Sept. 21, 25 deaths.
France: Paris, Sept. 10-28, 9 deaths.
Great Britain: London, Sept. 21-28, 163 cases, 6 deaths.
Italy: Naples, Sept. 21-28, 71 cases, 4 deaths; Palermo, Sept. 14-21, 1 death.
Mexico: Hunucma, Sept. 21, epidemic; Vera Cruz, Sept. 28-Oct. 5, 7 cases, 4 deaths.
Russia: Moscow, Sept. 14-21, 1 case; St. Petersburg, Sept. 14-28, 3 cases, 1 death.
Uruguay: Montevideo, July 27-Aug. 24, 71 cases, 10 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, Aug. 18-Sept. 1, 3 deaths.
Costa Rica: Port Limon, Sept. 28-Oct. 5, 8 cases, 3 deaths.
Cuba: Havana, Sept. 28-Oct. 5, 3 cases.
Mexico: Merida, Sept. 14-21, a few deaths: Valladolid, Sept. 14-21, epidemic; Vera Cruz, Sept. 21-28, 6 cases, 2 deaths.

PLAGUE.

Philippines: Manila, Aug. 25-31, 5 cases, 4 deaths.
Japan: Formosa, Sept. 7-14, 5 cases, 4 deaths.

CHOLERA.

Japan: Onsen District, Sept. 7-14, 1 case.
Straits Settlements: Singapore, Aug. 25-31, 1 death.

A FURTHER REPORT ON PERMANENT CATHETERIZATION.*

J. RILUS EASTMAN, M.D.

INDIANAPOLIS, IND.

Permanent catheterization in the male has been practiced by the writer in fifteen cases. In each case the catheter was retained for more than ten days, and in two instances for more than sixty days. These cases embraced a variety of conditions demanding bladder drainage, and in all but one entirely satisfactory results were obtained.

The fifteen cases included six perineal operations for stricture of the posterior urethra—one of which involved resection of nearly all of the pars membranacea—two operations for the closure of the perineal urethral fistulæ, two cases of perineal lithotomy, two cases of severe cystitis complicating prostatic hypertrophy, a case in which the catheter was introduced to drain and give physiologic rest to the bladder for the relief of atony and incontinence following stricture of the pars anterior, a plastic operation for the cure of a vesicorectal fistula, and another for the closure of an old unhealed suprapubic cystotomy wound.

An experience of fifteen cases is hardly extensive enough to justify the drawing of general deductions. The writer therefore submits the following points as mere impressions in the hope that a larger experience will establish their accuracy.

The mechanical urethritis occasioned by the presence of the catheter was in all cases insignificant. There was no complaint of urethral pain, and the discharge from the urethral mucosa was never annoying, usually just enough secretion of tough fibrino-muco-purulent character, accumulating during 24 hours, to form a thin ring upon the catheter at the meatus. The decidedly benign urethritis invariably became less active after the catheter had been in position for a few days. In two cases the catheter was retained without changing for two months, and in these, during the latter weeks, the discharge became practically nil. These facts suggest that the urethral mucosa develops a tolerance for the instrument after suffering its presence for a few days. In a few of the cases cited during the first few days permanganate of potassium in hot weak solution was injected between the catheter and the mucosa, but even when this measure was omitted the urethritis was slight. The catheters used were of soft rubber with two eyes. Large sizes were chosen for the reason that such catheters as completely fill the lumen of the urethra occasion less frictional irritation than smaller ones, which readily slide and twist in the canal. If a small instrument is used urine may escape freely from the perineal wound or find its way to the meatus between the catheter and mucosa. Prompt closure of the perineal wound and convalescence may be thus retarded. The penis will often by bending and writhing disgorge a small limber instrument, whereas a large catheter, because of its greater stiffness, is much more easily retained. The presence of the large catheter in the bladder-neck seemed to relieve irritability in this region. Severe muscular spasm or tenesmus never occurred during its use by the writer. Dilatation of the anal sphincters relieves irritability. Why, therefore, should not dilatation of the vesical sphincter produce a somewhat similar result? The catheters used varied in size from 26 to 29—Charrière scale.

The presence of a properly applied retention catheter should not produce cystitis. It has been stated that inflammation of the bladder may occur during permanent catheterization as the result of direct extension of an urethritis or from decomposition of the small quantity of urine which always moistens the intravesical end of the catheter. If cystitis was produced in either manner in the writer's cases it was not severe enough to occasion symptoms. Permanganate of potassium solution or a solution of hydrogen peroxid were occasionally introduced into the bladder, chiefly, however, for the purpose of eliciting assurance that the catheter was freely open. Regular flushing of the bladder was not practiced except in the two cases of cystitis complicating prostatic hypertrophy. Boracic acid in solution proved undesirable for irrigation in these cases, as its crystallization in the long-retained catheters partially obstructed the lumen. In the cases of cystitis pain and strangury were distinctly relieved by permanent catheterization. Guyon and Michon used the retained catheter in a large number of cases of cystitis attending prostatic hypertrophy, and in 77 per cent. a cure is said to have been obtained. It is essential to success in the treatment of cystitis that the catheter be introduced just far enough so that the tip bearing the eyes projects within the bladder and is accurately secured in this position. Pain and strangury suggest that the catheter has been introduced too far. The lumen of the catheter should be large enough to drain the urine from the bladder as fast as it enters from the kidneys.

It was noted that the pressure absorption produced by the continuous presence of the large soft rubber catheter was such as to remove extensive soft and hard infiltrations. After two weeks' retention of the catheter it was often easily possible to pass steel sounds several sizes larger than the catheter itself.

It is reported that occasionally during permanent catheterization with a metallic instrument abscesses develop in the peri-urethral tissues at the scrotal angle.

These have possibly been due to pressure exercised by the hard catheter. At any rate, no such complication has occurred within the writer's knowledge from the

Fig. 1.—Retained catheter, secured by two transfixing safety pins and two adhesive straps.

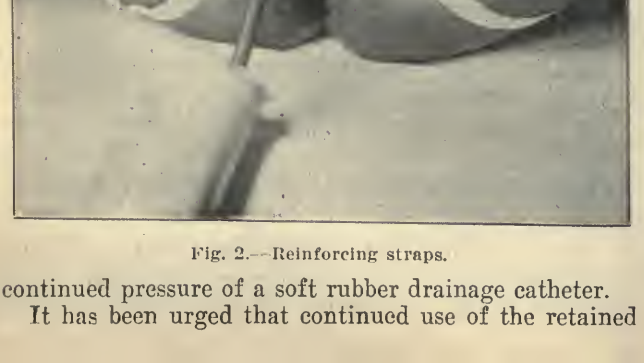

Fig. 2.—Reinforcing straps.

continued pressure of a soft rubber drainage catheter.

It has been urged that continued use of the retained catheter will conduce to atony of the bladder. This is certainly not a valid argument against its use in properly selected cases. If it puts at rest the bladder muscularis, perineal and suprapubic openings do likewise. Fuller, with others, has shown that rest in many cases of vesical atony, particularly those cases resulting from stricture, is a sovereign agent in treatment.

There are many good reasons why permanent catheterization should be selected as the method of choice for routine use in selected cases in draining the urinary bladder. Among these the following may be enumerated:

1. By its use the urine is removed by the natural exit.

2. If used after operations involving opening of the posterior urethra until the perineal defect is closed, the period of convalescence is shortened since the perineal wound closes promptly if the urine be drained through the urethra.

Fig. 3.—Transverse strap to hold the penis down.

3. The caliber of the urethra is maintained or even increased, and the subsequent passage of instruments is rendered easy.

4. Much of the tedious work of after-treatment, as sounding, becomes unnecessary or is decidedly lessened.

5. After perineal section involving removal of a portion of the posterior urethra, intermittent catheterization or sounding is exceedingly harmful and difficult of execution; hence, maintenance of the urethral lumen becomes a serious task. If, however, the retained catheter is used, sounding becomes unnecessary and the new segment of urethra has a guide over which to form itself.

6. The urine may be thus accurately drained into a receptacle, and bedsores, dermatitis and much discomfort are avoided.

7. The danger of uremic poisoning is reduced, since the area of the unprotected tissue with which the urine must come in contact is diminished. For the same

reason the danger of bacterial infection or intoxication is lessened.

8. Pain and fever are notably slight during permanent catheterization, if care be exercised that the instrument does not project too far into the bladder.

9. Soft and hard infiltrations which may narrow the caliber of the urethra are removed by the pressure absorption produced by the presence of the catheter.

10. Drainage of the bladder in cystitis may be accomplished by this method without subjecting the patient to a more or less dangerous surgical operation, as must be done when suprapubic or perineal drainage is employed; here also the possibility of delayed non-closing of the wound enters into the consideration. The catheter may often be introduced in such cases with as little pain and inconvenience as accompanies the introduction of Skene's catheter for permanent catheterization in the female.

A convenient method of retaining the catheter is as follows: After the introduction of the instrument it is transfixed with two safety pins just in front of the external meatus. To each of these pins is fastened a narrow strap of adhesive plaster with the glue side toward the penis. These straps fall naturally along the course of Poupart's ligaments and around the sides. They may, if necessary, be reinforced by two other straps, which should pass downward along the outer edge of each abdominal rectus muscle, crossing the first two near the sides of the root of the penis, and continuing downward between the thighs to the buttocks. If the penis turns upward it may be easily held down by an additional strap passed transversely over its dorsum, the ends of this strap being fastened to the skin of the buttocks or the posterior aspect of the thighs.

FALLACIES IN THE TREATMENT OF URETHRAL DISEASES.*

ROBERT HOLMES GREENE, A.M., M.D.

Attending Surgeon to Workhouse Hospital, New York City; Attending Genito-Urinary Surgeon to French Hospital.

NEW YORK CITY.

Looking backward over the history of the treatment of the diseases of the urethra, if one is impressed with the slight amount of real progress that has been made, there is less cause for surprise if the fact is taken into consideration that our knowledge of the nature itself of these diseases, certainly until the last fifteen years, has been very slight. Known in ancient days to be an entity by itself, urethritis came to be considered as another manifestation of syphilis from early in the sixteenth until the middle of the last century. Neisser's discovery of the gonococcus in 1879, and particularly the discoveries of Pasteur, Metchnikoff and others as to the nature of infecting diseases and the way the body reacts against them, have acted as guideposts, showing the way towards their proper treatment, although the information from this source as regards their treatment through a misrepresentation of the above-mentioned discoveries has sometimes proved misleading. One general law as regards treatment of the urethra that can easily be interpreted from the discoveries made by these later observers is, that measures tending toward the destruction of an invading organism in one portion of the body should be destructive towards organs invading any other portion of the system; the influences of such measures being modified by the character of the organism and the portion of the body attacked. Apparently some of the recent exploiters of rapid cures of urethritis have not taken this into account. If, however, an overwhelming mass of clinical observation show their measures to be correct, then it must be that our interpretations of Nature's laws are wrong, and upon the pathologists rests the duty of modifying their present explanation of Nature's phenomena. Thus the pus of urethritis is often considered in recent times to be the disease itself instead of a mere symptom of the conflict going on between the forces of the body and the invading microbe, and an effort of Nature to destroy, by means of the bactericidal serum, the invading organism, and to sweep them and the results of the conflict between them and the portions of the body away by its flow. Then again, some fifteen or twenty years ago, the so-called strictures of large caliber of the pendulous urethra were held accountable for many of the inflammatory affections of that membrane, and their incision recommended as a method of treatment. Operations for these running up into the hundreds in number were not infrequently reported. Two factors have probably caused these operations to fall into disuse: Clinical experience not having demonstrated from such measures the good clinical results that might theoretically have been expected, and the possession at the present time of a more definite knowledge as to what stricture really is. Roughly speaking, true organic stricture of the urethra is cicatricial tissue formed at the base of a granuloma in the urethra due to a change in the position in the normal cells from a horizontal to a vertical plane and their gradual lengthening. The granuloma is an infiltration of the round-cell type around and under the base of an ulceration or a dipping down of this infiltration in the urethral follicles, which ar much more numerous than has been generally considered the case; the dipping down of the ulceration being after-results of acute inflammatory diseases of the urethra. This cicatricial tissue may be, of course, much more quickly formed by external injury or careless instrumentation. If strictures as a routine matter are being incised at the present time less generally than a few years past, it is to be looked upon with commendation; for undoubtedly in the past, many cases of the above-mentioned granuloma which may cause swellings in the urethra have been mistaken for true stricture and unnecessarily incised. It can be stated as a fact that the chronic inflammatory conditions following urethritis in the urethra, both anterior and posterior, and in the

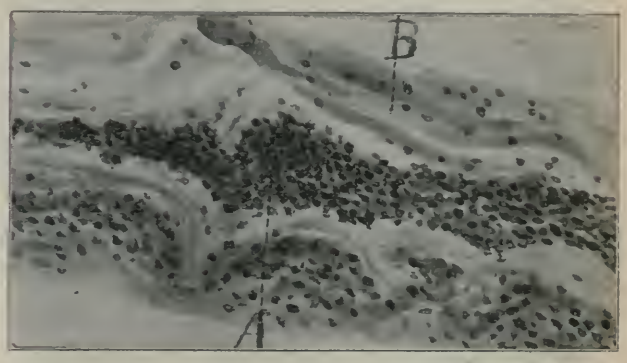

Fig 1.—Case 5, showing connective tissue hyperplasia about an acinus which has become filled with an inflammatory exudate. Section taken from the peripheral portion of an enlarged gland removed by operation. *a*, Inflammatory exudate of small round cells; *b*, hyperplastic connective tissue fibrils. This represents the acute infiltration of the acini, similar to what is seen in prostatitis associated with urethritis.

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker and A. J. Ochsner.

prostate, proceed in a slow method. The writer's experience has been that outside of the traumatic cases above mentioned, strictures of such resiliency following urethritis as to require a cutting operation are almost never met with, certainly not in men under 40 years of age. To be sure, in hospital practice he has, like all surgeons, found a series of cases with a mass of cicatricial tissue in the deeper portions of the urethra of such resiliency as to require incision in order to give the urethra a proper caliber, but these have been cases that have given the history of antecedent operative procedures that were apparently unnecessary, and the patients have been men who have been careless of their well-being and have not attended to measures necessary to keep their urethras properly dilated.

The discovery of the gonococcus apparently suggested to its first advocate the so-called irrigation method of treatment for acute urethritis, the disease being considered at this time as being generally confined to the anterior urethra alone. Within the past few years it has been demonstrated as the result of observations made by several men, of whom the writer is one, that urethritis not rarely but generally invades the deep urethra and prostate and not the anterior urethra alone. These dis-

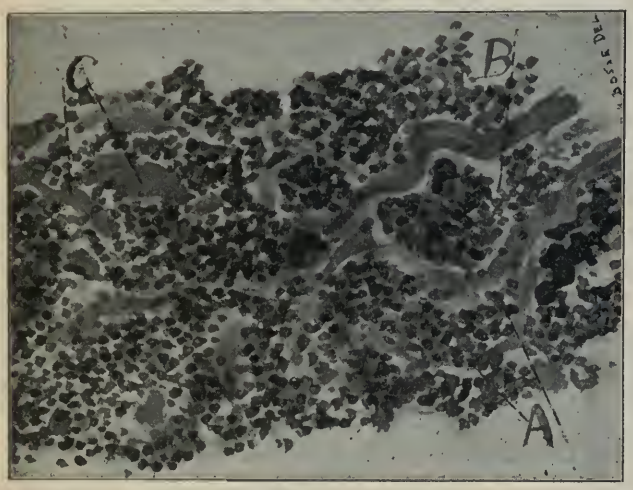

Fig. 2.—Case 30, showing an extreme small round cell infiltration in the immediate neighborhood of the posterior urethra. The central portions of this gland showed a great interstitial hyperplasia with the cell infiltration becoming more and more marked, until the area pictured was reached. *a*, Small round cells; *b*, acini filled by exudate; *c*, stroma, largely obscured by the cell infiltration. This represents a later stage of same condition as shown in Fig. 1, where the acute process still continues.

coveries as to the nature of urethritis have had an important bearing upon the treatment of urethritis in two particulars. It has obliged those who believe in the irrigation treatment of acute urethritis to recommend the extension of irrigations to the deep urethra and bladder, in order to be logical. It renders illogical at once the position adopted by the earlier advocates of the irrigation method who recommended the irrigation method for the anterior alone, and illogical as well, the position of those who still advocate the use of injections to the use of anterior urethra alone by the patient, and illogical also the position of those who recommend the use of recurrent irrigations from the bulbus urethræ out. The above refers, of course, to acute urethritis and is not meant to refer to the local treatment of some chronic lesion remaining after acute inflammatory processes have subsided. The believers in irrigation methods of treatment of acute urethritis received a powerful recruit a few years past in the person of Dr. Janet, whose method of irrigation by permanganate of potash has had so many followers in this country. Theoretically, the advocates of these methods are, according to the laws of modern pathology, in error, their idea apparently being either that the gonococcus can be killed by direct administration to it of some substance inimical to its existence, or that the soil may be rendered unsalubrious for it to breed upon, or that the substance injected being kept continually present on the urethral wall, when the gonococcus emerges from the deeper layer of the urethra, it is there to put an end to its career; or, as one of the advocates of recurrent irrigations suggests, the gonococcus can be knocked off the walls of the urethra and washed out at the same time.

The above seems to be the sum total of the theoretical explanation of the good results which advocates of the early irrigation treatment of urethritis claim to obtain; for all evidence as to the presence or absence of the gonococcus obtained from staining methods alone is of comparatively little scientific value, unless the results are confirmed by cultures. Eight years ago the writer claimed that local treatment for urethritis should not be commenced until the acute symptoms had subsided; that is, from six to eight weeks after the onset of the disease. His belief, at that time, was founded on clinical experience and conformed to the pathological

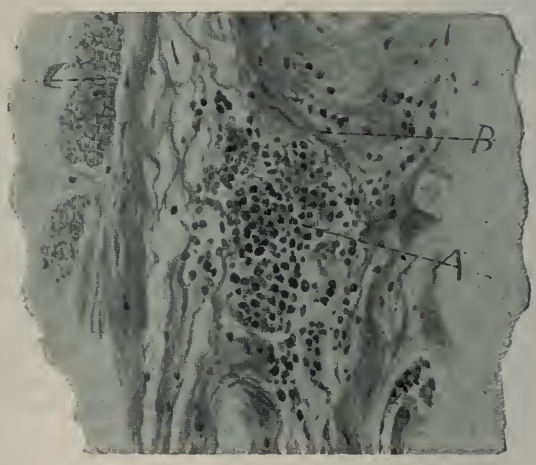

Fig. 3.—Case 1, showing moderate round-cell infiltration, with marked interstitial increase. Taken from central portion of gland. Tissue removed by operation. *a*, Patch of round-cell infiltration: *b*, hyperplastic connective tissue; *c*, normal smooth muscle fibers, transverse section. This represents condition as shown in Fig. 1, where the process has become chronic, the muscular fibers surrounding the acini are being replaced by connective tissue fibrils.

laws as at that time understood. Recent discoveries in pathology and his further experience in dispensary and hospital work have tended to render them more positive. The list of genito-urinary surgeons who hold the same belief comprises many prominent men and seems to be increasing in size. Such wonderful results, though, are claimed to be shown by clinical experience by the advocates of irrigation methods in the early stages of urethritis, that their claims must be considered seriously, although their views are not apparently in conformity with pathological laws, nor is the evidence furnished by them as to the presence or absence of the gonococcus by microscopical examinations of the secretions alone, of scientific value. It seems there must be some fire where there is so much smoke. It tends to discredit somewhat, to an unbiased mind, belief in the views of those who claim that acute urethritis is an ephemeral disease capable of being cured in a very few days by any process of irrigations, to find that the advocates of such irrigations differ so widely as to the proper material to be used for

their solution. The list of such substances is only partially filled by the mention of permanganate of potassium, mercurial, ichthyol, etc., ad infinitum.

There is some evidence which goes to show that they render the patient more comfortable by these methods; that a purulent discharge is more quickly changed into a muco-purulent one; and that the gonococcus sooner disappears from the surface of the urethra. The writer is of the opinion, however, based on his clinical experience as well as on any theoretical pathological knowledge of the disease that he may have, that by these methods the gonococcus or whatever form of microbe may be causing the inflammation, instead of being allowed to have its battle with the forces which the body marshals to said microbe's destruction, is driven into the deeper portions of the urethra and the prostatic follicles. By the use of these methods the tendency to what is termed latent urethritis, that is, the recurrence of urethritis without reinfection even years after the original invasion of the disease—a condition which is recognized by all observers on this subject—is increased. The observations of many people extending over a long

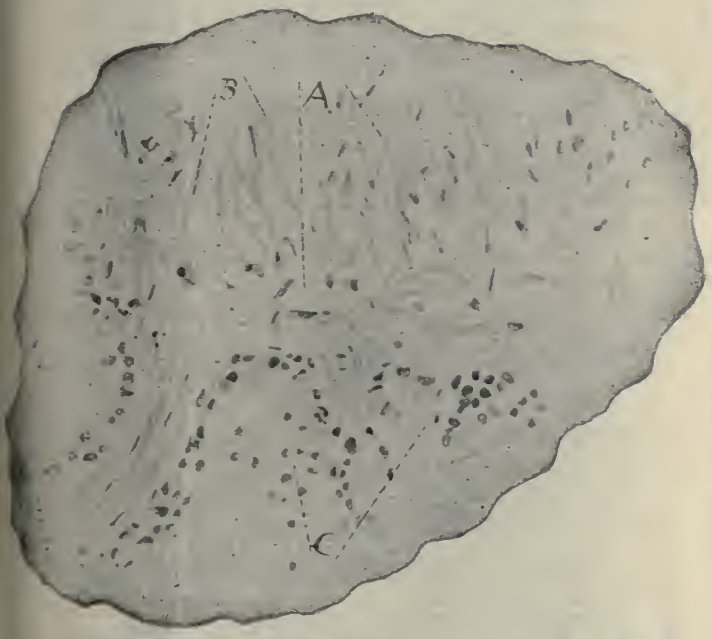

Fig. 4.—Case 28. Moderate prostatic hypertrophy in man of 53 years. Showing increase in interstitium, separation of muscle fibers and proliferation of the epithelial cells of acini, some of which are completely filled by these cells. *a*, Hyperplastic connective tissue; *b*, normal muscle fibers; *c*, proliferating epithelial cells, almost completely filling the acini. This represents a form in which the inflammatory process has caused a rapid proliferation of the epithelial cells of the acini and a production of connective tissue which has displaced the muscle cells to a considerable degree.

period of time will be necessary to entirely substantiate the value of the opinions held by those who believe in the postponing of local treatment for urethritis until after the acute stage has subsided. The frequency with which infection entering through the urethra breaks through the barriers set up by Nature, such as the bactericidal serum, the phagocytosis and the chemotactic action of the nuclei with the ptomain given off by the invading bacteria, should be closely studied; and fortunately, it is just now a subject which is occupying the attention more and more of the medical world. The frequency of the diseased condition of the female in the ovaries and oviduct, in the prostate and testicles in the male, in the bladder, ureters and kidneys in both sexes, blood infection which may or may not affect the heart, meningitis, conjuctivitis and certain other diseases of the eye that are due to infection from the urethra, should be ascertained with much more positiveness than our knowledge at the present time informs us. In the earlier part of this paper the writer stated that the treatment of urethritis should be based on our present knowledge of the character and extent of the disease. Urethritis being shown to generally extend to the urethra and prostate in the form of a granulomata in the urethra, later causing cicatricial tissue stricture, which rarely requires an operation by incision. Antecedent traumatism only generally through instrumentation or previous cutting operations, necessitates it in a man under 40. The best treatment of acute urethritis for the first six or eight weeks, at least, is to refrain from local measures; leave it alone, like an infected wound occurring at the bottom of a long narrow sinus of any other part of the body. The chronic urethritis should

Fig. 5.—Specimen removed at autopsy from an old man. History of chronic urethritis. Gland much enlarged. Large corpora amylacea in acini from which all epithelium has been removed. Increase of interstitium, atrophy of muscle. Areas of inflammatory infiltration. *a*, Corpora amylacea; *b*, areas of inflammatory exudate. This is one way in which the condition shown in Fig. 4 can terminate. Degeneration of the epithelial cells has caused the formation of large corpora amylacea, and the irritation of these has produced the surrounding inflammatory reaction.

be treated locally, carefully and for a long period of time. The irrigation method of treatment for acute urethritis is wrong; it increases apparently the prostatic infiltration and the danger of the recurrence of the inflammation from latent urethritis, although it may render the patient more comfortable, and more rapidly change the purulent inflammation in the muco-purulent one. It has been demonstrated that a chronic prostatitis following urethritis is an extremely common occurrence. Any observer, by carefully washing out the bladder in a case of acute urethritis, massaging the prostate and examining the few drops of secretion mi-

croscopically that the patient is able to pass immediately afterwards—although he will not in every case obtain secretion enough—will find that the secretions will contain substances which show an infiltration of the inflammation into the prostatic follicles. Dr. Gouley in his last book on genito-urinary diseases as a result of autopsies performed on those who had had chronic prostatitis following urethritis and who died of some intercurrent diseases, states that "a granulomatous inflammation was found dipping down in the prostatic follicles and tending to close up the mouths of the ducts." Apparently it is the same kind of granuloma as is associated with the granuloma found in the urethra which is the antecedent cause of stricture, and like all inflammations following urethritis of a slow grade of inflammation.

The writer, in a paper read before the American As-

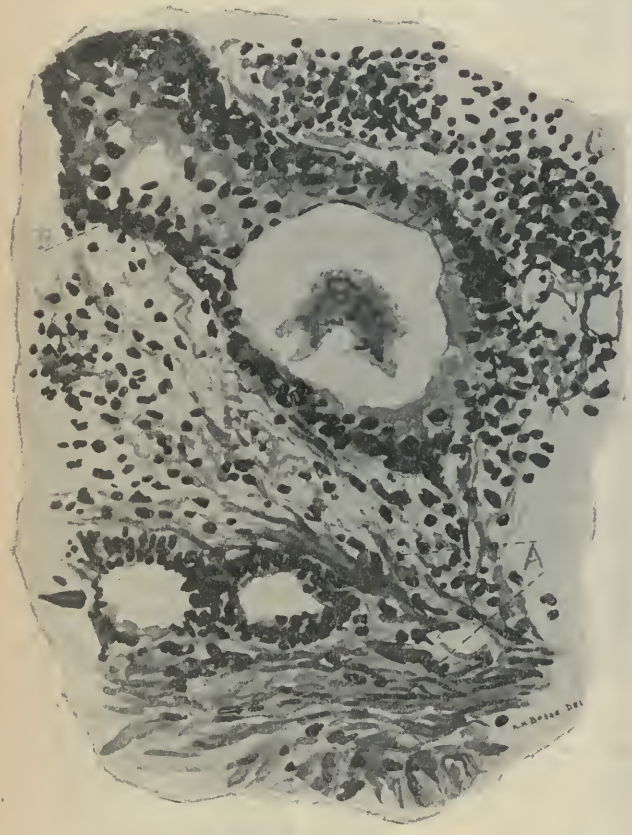

Fig. 6.—Case 32. Greatly hypertrophied prostate removed by Dr. Lilienthal. Showing marked increase in the connective tissue elements *a*; epithelial cells partly filling acini *b*; and inflammatory exudate about acinus *c*. Another way in which the process shown in Fig. 4 can terminate. The final stage of this type results frequently in the "small, hard prostate."

sociation of Genito-Urinary Surgeons three years ago at West Point, showing the frequency of prostatitis in connection with urethritis and as the result of some clinical experience, expressed the opinion that urethritis was the cause of prostatic hypertrophy of the aged. He expressed his views later in a paper read before the Academy of Medicine in New York. During the last hundred years the list of the names of observers who have believed that urethritis was the main cause or one of the causes of prostatic hypertrophy of old age has become a long one, and space does not admit of their mention here. Autopsic evidence, however, seemed to be against it, for the enlarged prostate examined microscopically in sections was shown by scientific observers to be generally an adenoma, and not due to an increase in connective tissue growth as might have been expected. The small hard prostates, however, showed an increase in connective tissue growths. The books have also mentioned the

Fig. 7A.—Case 31. Greatly enlarged prostate removed by Dr. Guiteras. Outline sketch showing cystic acini, the so-called "cystic adenoma of the prostate."

Fig. 7B.—Section of wall between these acini, showing great decrease in the amount of muscle and hyperplasia of the connective tissue elements. *a*, Cystic acini, produced by obstruction of the ducts which have been produced by pressure of the inflammatory process about them; *b*, hyperplastic connective tissue fibrils, representing the chronic inflammation; *c*, atrophic muscle fibers, compressed by overgrowth of interstitium. This represents the same character as Fig. 6. That is, cystic distension of the acini instead of formation of large corpora amylacea as shown in Fig. 5. Enormous connective tissue increase surrounding acini and taking place of muscular fibers.

prevalence of a prostate in which the growth consisted of an increase in muscular tissue. A few weeks ago the

attention of the writer, through the kindness of Dr. B. Lapowsky, was called to an article written by Prof. Stanislaus Ciechanowski[1] on the anatomy of prostatic hypertrophy. Ciechanowski's researches have been most exhaustive in character, and after studying sections made from many diseased prostates he states as his opinion that the prostatic hypertrophy of the aged is an inflammatory disease; that if the original focus or the inflammation is towards the periphery of the prostate an increase in connective tissue will take place and give rise to the small hard prostate; if more central, that is, if the inflammation invades the mouths of the ducts, the larger and softer variety of enlarged prostate would be formed which resembles an adenoma and is easily mistaken for that. The prostate with an enlargement consisting mainly of muscular tissue, he failed to find in his investigations, nor was one found of this type in the investigations carried on at his suggestion by Dr. Brooks. Ciechanowski states that finding all the enlarged prostates examined by him to have an inflammatory origin, he thinks urethritis must be held accountable on account of its great frequency as a producer of inflammation in that region. The writer was so impressed with the conclusions of Ciechanowski that he requested Dr. Harlow Brooks, the eminent pathologist of the Bellevue and University Medical School, to carry on some investigations in the manner of Ciechanowski to see whether the latter's conclusions would be affirmed or disproved. Dr. Brooks kindly consented to do this work purely from a scientific interest which he took in the subject, and through his efforts and the writer's a large number of prostates in a comparatively short space of time were fortunately procured. The plates shown represent sections through some of the hypertrophied ones in this collection and it is hoped their study will illustrate the nature of the growth better than an exhaustive description. The writer here desires to express his thanks to Dr. J. P. McGowan of New York City for the use of a collection of nearly seventy prostates which Dr. McGowan had accumulated and on which some microscopic work had been done by Dr. Smith. Quite a number of the prostates in this collection were enlarged. Through the kindness of Dr. Charles Peck sections from six enlarged prostates, which had been removed and of which the histories could be obtained, were secured from the museum of the New York Hospital, and his thanks are likewise due to Dr. J. P. Tuttle, New York City, for a prostate removed at an autopsy, and to Dr. Howard Lilienthal and Dr. Ramon Guiteras for a prostate each had removed at an operation and concerning which the history of the patients could be obtained. Dr. Brooks was also enabled to obtain quite a number of prostates. In all nearly a hundred prostates were placed at the disposal of Dr. Brooks; of these thirty were enlarged, and of quite a large proportion of these latter the histories could be obtained. Dr. Brooks, to whom the writer feels the main credit for the outcome of these investigations belongs, reports as follows:

In accordance with your suggestions I have made a careful microscopic study of thirty specimens of hypertrophied prostate glands. The studies were made with special reference to the conclusions recently reached by Ciechanowski in his elaborate study of this condition.

The specimens studied by me comprised nearly every variety of enlarged prostate, including several of the so-called cystic adenomas, but excluding cases in which the enlargement was clearly of neoplastic origin, i. e., as carcinomata, etc.

In all of the specimens studied, inflammatory changes were clearly evident. The character of these lesions varied in the several cases from a chronic interstitial hyperplasia with more or less small round-cell infiltration, to actual suppuration and necrosis. In most of the specimens the inflammatory process noted was clearly of a vascular origin and in the acute cases could be traced in several instances direct to extension from the posterior urethra or from the ducts and acini of the prostate gland.

Apparently in most of the cases the hypertrophy was the direct result of the inflammatory changes, manifested in hyperplasia of the connective tissue, muscular atrophy and cell infiltration.

The study of these cases leads one to the conclusion that at least most forms of prostatic hypertrophy, including the so-called cystic adenoma, are of inflammatory origin and are in no way of the nature of new growths. The type of hypertrophy resulting depends on the location and character of the primary inflammatory process; as to these points I am in full accord with the opinions advanced by Ciechanowski.

One is not justified in drawing such sweeping conclusions from a study of so few cases as have been at our command in the brief period which has been allowed us, but taken in connection with the extensive studies just mentioned, I think we may look on this confirmatory evidence as almost conclusive.

I wish again to call your attention to the fact that at the outset I was not at all prepared to accept the decidedly radical conclusions of Ciechanowski, but careful study of the specimens which we have collected has won me to his view. Enclosed with this brief general report you will find a detailed report of my findings in each specimen.

It would not be claiming too much to conclude from these investigations that prostatic hypertrophy is an inflammatory enlargement and that urethritis, while perhaps not the only, is its most frequent causative agent. The question of urethritis in marriage, the question as to how extensive it is in its systemic effects, whether it is a simple ephemeral disease in the vast majority of cases capable of being quickly cured in a few days by the early administration of irrigations, as the believers in that form of treatment claim, or whether it is often a more deep-seated affair subject to the same pathologic law as allied diseases, as is believed by the writer, among others, are questions, the positive solution of which would be of great value to the medical profession and to the commonwealth. It is not from any one genito-urinary surgeon that a true answer to all these questions can be expected, but it can only be by the combined good scientific work of specialists in all diseases of general practitioners and pathologists that these problems can be solved.

In conclusion the writer can only reiterate what he has previously said, that we have, in his belief, in urethritis a disease often serious in character, far reaching in its results; apparently established by Nature or God, as you will, as a punishment for immorality; and is one among many of the signs which Nature presents, which tend to show that in domesticity and the proper fulfilling of the marriage vows, the laws of Nature and the moral law are closely allied.

Classification of Mental Diseases.—The Italian neurologists and alienists in congress assembled at Ancona in October, adopted the following classification as best adapted for statistical purposes: 1, congenital psychoses; 2, acute and simple; 3, chronic, primary and consecutive; 4, paralytic; 5, accompanying a neurosis; 6, toxic, and 7, infectious.

NEW METHOD OF SKIAGRAPHIC DIAGNOSIS FOR RENAL AND URETERAL SURGERY.*

G. KOLISCHER, M.D., AND L. E. SCHMIDT, M.Sc., M.D.
CHICAGO.

Skiagraphy for medical purposes was especially advanced and perfected in America. Calculous deposits were especially attractive for *x*-ray diagnosis. McArthur, Bevan, Leonard and others four years ago showed the necessity of skiagraphs in all suspected cases of renal stone. Our method, now to be described, will perfect the knowledge of the topography of the kidney and ureter, the location of calculi and aid in important differential diagnoses. A conservative and plastic surgery of kidneys and ureters has lately made such progress and achieved such good results—we refer especially to Fenger and McArthur cases—that the absence of such diagnostic measures was the stimulus for our work. To a limited extent the different methods of collecting urine from each kidney and the cystoscopic observation of the ureteral openings has satisfied this desire. Skiagraphs frequently show the kidney-shaped shadow of the kidney while the representation of the ureters on the plate naturally failed on account of the delicate structures of these tubes. But, by the introduction of a suitable *x*-ray absorbing material into these organs with a simultaneous skiagraph, results of the highest value may be obtained and diagnostic problems solved that hitherto have been obscure. The technique is as follows: For locating the ureteral openings in the bladder and sounding the ureters in most of the cases we use Brenner's cystoscope; only in a few cases, where special peculiar conditions prevailed, we resorted to an improved modification of Casper's cystoscope.

Extensive cadaver work convinced us that the most desirable material for the sounds is lead, blended with some antimony. This kind of lead-wire is extremely flexible, so that the natural course of ureters would not be changed by introducing the sound. These sounds are soft and their surface polished up to perfect smoothness, so that injuries to the lining of the renal pelvis and of the ureter are not to be expected, and, in fact, are not to be observed, as careful examination in cadavers has proven.

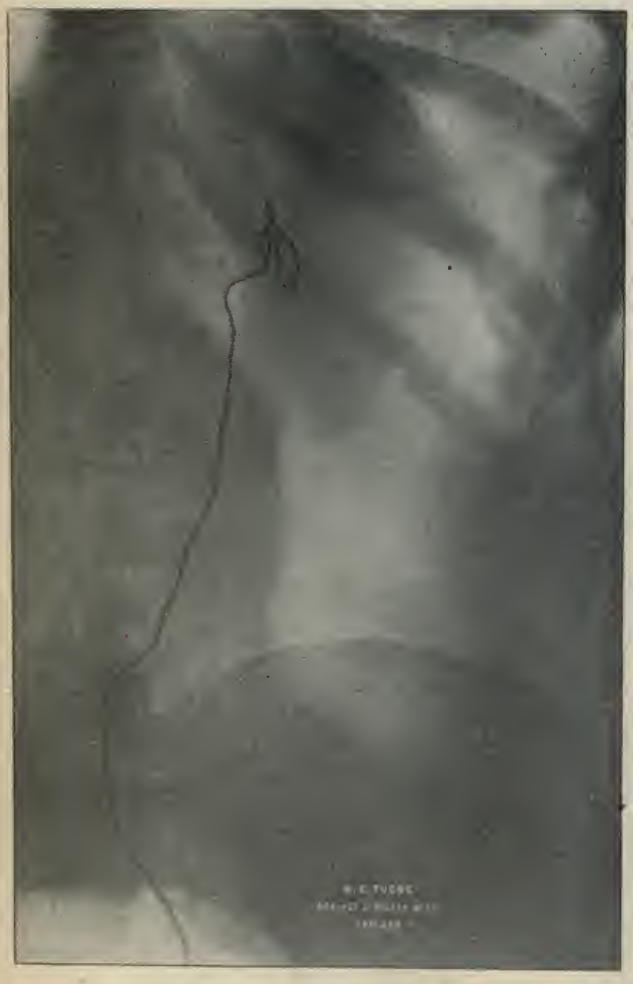

Fig. 1.—Cadaver experiment.

Fig. 2.—Tangential insertion of ureter and dilated renal pelvis.

If you free the ureter by dissection in a cadaver, its course is not changed by the introduction of our sounds, unless excessive force is used. On the other hand, this wire is sufficiently strong not to be torn by its movements through the canal of the cystoscope.

Our results and the diagnostic possibilities of our methods can best be discussed on examination of the pictures which we present. We desire to say that we selected a number of cases as representative types of certain pathologic conditions. The first two pictures are taken from a cadaver and show that, although the sound was pushed up with all possible force, the course

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker and A. J. Ochsner.

of the ureter was not materially changed; at the same time it can be seen how the end of the sound curls upon itself in a dilated pelvis, thus outlining the renal pelvis.

The next picture is taken from the living and shows: 1, tangential insertion of the ureter; 2, a dilated pelvis outlined exactly by the wire. These conclusions have been verified by the findings during the operation, performed on account of suppuration in the kidney.

The next picture shows what we would determine as cicatricial distortion and consecutive partial obstruction of the right ureter. This patient met with a railroad accident some years ago, resulting in fracture of the pelvis. After dismissal from the hospital symptoms of intermittent hydronephrosis set in and still prevail. The sound can not be passed above the pelvic brim and

Fig. 3.—Ureteral obstruction.

the skiagram shows a decided deviation of the ureter. There, where the tip of the sound is to be seen, is evidently the seat of the obstruction, and there must be the field of operation.

The next picture shows a stone in the parenchyma of the kidney.

We desire to call attention to the diagnostic features of this case. We see distinctly the distance between the tip of the sound and the calculus, this distance corresponding with the distance of the location of this stone from the renal pelvis. In fact, this patient was operated on some time ago by a Chicago surgeon on account of serious renal symptoms. The pelvis was split open and no stone was found, and even acupuncture failed to reveal the seat of the suspected stone. If this patient will be operated on now, an operator equipped with one of these skiagrams will hardly fail to find the calculus.

The next two pictures are taken from a female patient suffering from floating kidney. These pictures give us some valuable information.

Judging from the outlines of the kidney and the insertion of the ureter, we can see that not only a descensus of the kidney has taken place, but also a rotatory dislocation. Considering these conditions it can be easily understood how temporary obstruction is produced in such cases. The second picture was taken after the kidney was pushed further down. We see how the ureter, in order to follow the excursion of the kidney, was forced into a double curve.

Fig. 4.—Stone in parenchyma of kidney.

At the same time, we wish to show the skiagrams of a kidney and a renal stone, pictures which were taken without previous sounding of the ureter, so that these skiagrams have to be judged upon without the guidance of the ureteral sound. The difference of the diagnostic dignity between such skiagrams and ours is obvious.

If we sum up the results and possibilities of our method we can state our method is free from danger. We can determine the course of the ureters, and the location of renal pelves; we can diagnose dilatation of the renal pelvis; we can determine the location of renal calculi. We are able to determine the seat of an ureteral obstruction, and we are in a position to judge to a certain extent upon the nature of the ureteral obstruction.

We have the possibility of differentiating gallstones from renal stones, which differential diagnosis occasionally is a very hard one, or even impossible to make by other means.

Fig. 5.—Floating kidney, high up.

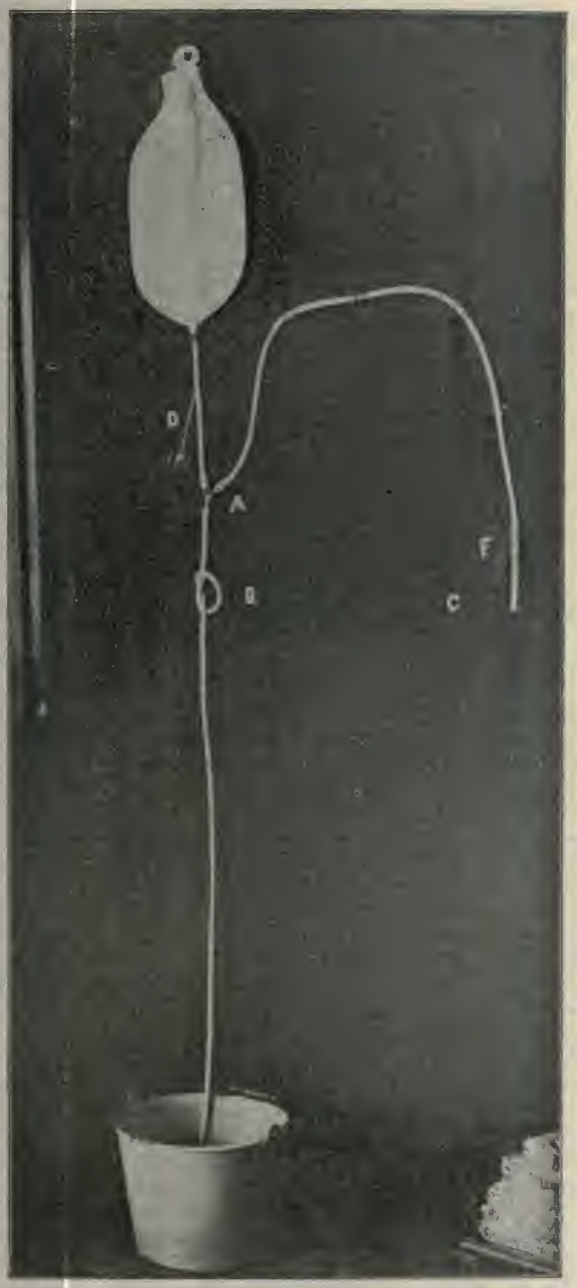
Fig. 6.—Floating kidney, low down.

We have the possibility of distinguishing between non-renal neoplasms and dislocated and enlarged kidneys.

In all cases where a surgical kidney can not distinctly be made out by bimanual palpation, cases which quite often present greatest difficulty in finding the kidney after incision was made, our method will give most valuable information concerning the topographical location of the kidney.

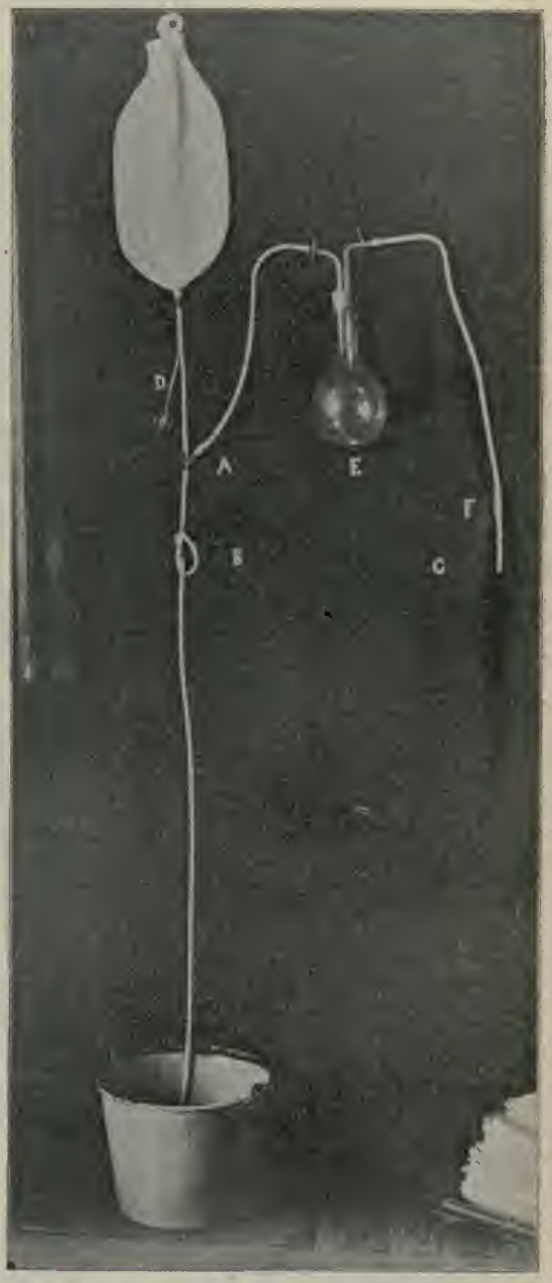
Fig. 7.—Ureteral stone without wire insertion.

Fig. 8.—Kidney stone without wire insertion.



We would like to appeal to our professional colleagues to use this method. for we are positive it means an im-

provement in our diagnostic means and that extensive use of this method will enlarge its possibilities.



In conclusion we wish to state that Mr. W. C. Fuchs of Chicago has done all our *x*-ray work.

DISCUSSION ON PAPERS OF DRS. FULLER, SYMS, GUITERAS, EASTMAN, GREENE, KOLISCHER AND SCHMIDT.

DR. R. H. M. DAWBARN, New York City—I should be very glad to devote the time allotted to me in opening the discussion to the papers themselves alone, but I have decided, with the consent and approval of the Chairman, to spend my time in demonstrating an apparatus, so simple, for suprapubic drainage, that I think I might say it is pretty nearly ideal. That is a subject, of course, germane to that which we are discussing, of bladder and urethral surgery; I do not intend to take up the question (suprapubic drainage), but assuming it is to be employed, I think I can demonstrate to you that this method is thoroughly satisfactory. I have used it now about ten years, and it is not as well known as it ought to be outside of New York, although Dr. Weir of New York, and a few others here present, have employed it and will speak well of it. Ten years ago to-day, while I was enjoying my misery in a dental chair, it occurred to me that the principle then being used to keep my mouth dry could be used as well in other cavities requiring drainage up-hill. Twenty-five years ago, a dentist of Buffalo, named Dr. Snow, who is now dead, devised this method. Up to that time wads of bibulous paper had always been packed against the salivary ducts to keep the mouth dry. Dr. Keen of Philadelphia, Cathcart of England, Walker of New York, myself and others, have thought out and used modifications of this thing. The principle, however, belongs to Dr. Snow of Buffalo. The principle is that of intermittent syphonage, and it is not that of the Sprengel air-pump, as you might at the first glance suppose. The only points upon which I can lay claim to originality are the employment of simple and inexpensive means. A large fountain syringe, and a hard rubber

Dr. Dawbarn's method of suprapubic bladder-drainage. A, the Y-tube of vulcanite rubber. B, the "trap:" this is made by simply tying a knot; Dr. Dawbarn's method. C, a catheter with end cut off, thus making two eyes. D, artery forceps; a fountain syringe catch does as well, to regulate the flow. F, short piece of larger tubing; between this and the catheter air enters the bladder freely.

Dr. Dawbarn's method of suprapubic bladder-drainage. Showing a vacuum-bottle introduced into the circuit. E, bottle with rubber stopper and two glass tubes. This is used temporarily, at any time, to reckon the flow of urine per hour, and to analyze it undiluted by fluid from the reservoir.

Y-connection, the latter costing 20 cents in New York, are the only essentials, though I commonly add to this a soft rubber catheter of good size, as being less likely than other rubber tubes to become obstructed by accidental pressure. The glass trap employed in the other named inventions is quite needless and has obvious objections. While thinking over the matter it occurred to me that a trap is the same in principle and in effectiveness whether curved as usual, and as we see it always beneath every washstand, in towns, or whether instead it is quite differently shaped as the accompanying photographs indicate. Then the idea occurred of making such a circular trap and also having it self-retaining in that shape by just tying the simplest of all knots in the exit tube of the fountain syringe.

A trap is absolutely essential to the plan. By the catch just above the Y in the figure (which may be an artery forceps, or instead the clamp coming with every fountain syringe, removed from the tube and snapped upon its side, we regulate the speed of flow to drop by drop. When the trap is thus filled, the next drop starts a sudden syphonage of it, which in turn creates a vacuum between it and the bladder, and empties the latter. As often, then, as the trap empties, the bladder is evacuated. Commonly we regulate the flow so that this occurs every five minutes or so; the nurse need only refill a four-quart syringe a very few times daily. The apparatus can in practice be relied upon to maintain, if the patient is supine, a dry bed, and this with comfort to him; that is, the emptying of his bladder will not cause him pain.

It is necessary, however, to permit ordinary atmospheric pressure upon any urine in the bladder, or the apparatus will not empty that viscus. Hence a short piece of larger rubber tubing (shown in the illustration) is loosely slipped over the catheter, where it passes through the abdominal and bladder walls, and the two tubes are fastened together at one or two points by a stitch. Between them air passes in. The outer tube is held in its place as follows: Pass a long narrow strip of zinc oxid adhesive plaster from trochanter to trochanter across the abdomen where it crosses the wound, fasten it by a stitch to the side of the outer tube, just described.

The catheter is cut across between tip and eye and thus two openings into its lower end are arranged for. This has the same advantages that double-eyed stomach tubes possess. A point which I especially like about this drainage apparatus is the ease with which by it one may wash out the bladder; and practically always where we do suprapubic cystotomy this is advisable for a few days at least. It is only necessary to untie the knot—which is the trap—and alternately to pinch the tube below and above the Y. Pinching below, the water flows speedily into the bladder, pinching above, it empties the bladder as quickly. It is as simple a means as possible for washing out a stomach or a bladder in ordinary office work.

Finally, we wish occasionally to estimate the amount of urine that runs per hour, and to analyze it undiluted by the fluid from the fountain syringe. To do this, put into place between the Y and the bladder any large bottle with a tight rubber stopper pierced by two glass tubes. Thereupon, of course, this bottle becomes a vacuum and the urine passes from the bladder into it.

The only device used for the exit of urine by the suprapubic route which, as it seems to me, at all competes with the drainage device which I have been describing are the De Pezzer tube, the plan of Blasucci, and Dr. Gibson's, of New York, suggestion to use on the bladder the Kader gastrostomy idea, of a catheter sewn to the bladder walls so as to run obliquely through them. All of these plans have this in common, that in case the catheter is obstructed—it may become from thick ropy mucus, blood, pus, or calcareous deposits—washing out the bladder is much more difficult and ineffective because of the lack of free atmospheric movement within.

If, instead, the present plan is substituted I do not believe any surgeon will fail to be struck by its practical advantages.

DR. A. E. ROCKEY, Portland, Oregon—The operation of prostatectomy has been an evolution. It began first by cutting out large masses through large incisions, by retractors introduced into the bladder where the operations were done by sight; but the present plans, brought down to a scientific procedure, have given us entirely different methods. That method which will accomplish the object, which is the removal of the obstruction with the least interference of the tissues, will prove to be the best method. I believe that what Dr. Fuller has said about the passive indifference comparing it to the former indifferent treatment of appendicitis has come to be true in regard to prostatectomy. I believe it is incumbent upon the general surgeon to-day to give more attention to this subject. All who have given the subject careful attention know that these cases go year after year until they are almost too bad to be reached, and then either die or come to a radical operation. Now, then, the question for us to decide is, what method shall we adopt? Dr. Guiteras and Dr. Syms have described their technic and Dr. Fuller has described his in his book. In the January number of the St. Louis *Courier of Medicine* (1900) I described the method that I had been using for some time. It is what might be called a recto-vesical method, although at that time I had my assistant place his fingers in the rectum to raise the prostate. Previous to that time I had quite an unusually large number of large glands, more than subsequent experience has demonstrated to be the rule. The method I used was that of a combined morcellation and enucleation. Guiding the instruments with the index finger of my left hand, while an assistant raised the prostate from below and then cutting and tearing with the forceps and scissors in the right hand, in addition to the enucleation made with the finger. Since that time I have modified my technic until it is practically as described by Dr. Guiteras, without the use of perineal drainage. There are some differences in the method I use, as compared with those of Dr. Fuller and Dr. Guiteras, and as we are working together for the development of a satisfactory plan I trust I may be pardoned for taking the time of the Section to describe the technic that I employ. I now universally use a very small incision. It is not necessary in an ordinary case to make an incision over an inch and a half long through the integument and between the muscles, and the incision in the bladder I think is seldom more than an inch in length. Through an incision of that kind you can pull a prostate an inch and a half or two inches in diameter. The gland is usually soft and the bladder elastic. In the occasional instances of fibroma of the gland morcellation as previously mentioned may be done through the small incision. I hold a small-bladed scalpel vertically, and push down through the tissues and make the incision to the bladder in one cut in an upward direction; then push up the prevesical fat with the finger, or divide the lower portion with another touch of the scalpel. The next move is to catch the bladder in the center with a pair of bullet forceps, which is passed to the assistant who draws it to the opposite side. With a Martin needle armed with heavy silkwormgut I make a vertical stitch through the entire bladder wall of about half an inch in the direction of the incision and bring the needle through the abdominal wall and tie one knot without pulling it too tight. Then tie another loop above this through which the safety-pin retaining the drainage tube may be passed. I will illustrate this on the blackboard. The same process is repeated on the other side. The bladder is now well anchored with these stitches. With a quick, downward cut a vertical incision about an inch long is made into the bladder, and the index finger of the left hand inserted for exploration. If stones are present they are removed at once, and the debris thoroughly washed out. If there are no stones present a pair of straight hysterectomy scissors is inserted alongside of the finger, the tip of which rests in the urethra. The blade is pushed well into the urethra, the other one resting back of the gland, and a firm vertical cut is made. The scissors are then laid aside, the left hand removed, and pushed into a rubber glove which is held ready by a nurse. Two fingers of the gloved hand are now inserted into the rectum and the index finger of the right hand is pushed firmly into the intravesical incision in the gland, and the division line of the capsule sought for. When this is found it is almost always possible, by the bi-manual manipulation, to

enucleate the gland in one piece without any other instrumentation. In a few cases morcellation and excision by the scissors of portions which can not otherwise be detached must be resorted to. Cases of this kind, however, I think do not occur oftener than one in ten of those that come to operation. After the enucleation of the gland I insert a large drainage tube to almost the depth of the base of the bladder and fasten it by safety-pin through the loops previously mentioned. This is connected by a long tube passing to a pan under the bed. The method of suspending the bladder brings the inverted outer side against the tube like a valve and usually promotes a syphon drainage. The device described by Dr. Dawbarn would undoubtedly be of additional advantage in this method. I have resorted to perineal drainage as advocated by Dr. Fuller and Dr. Guiteras in but one case. My experience with suprapubic drainage as described here has been so satisfactory that at present I am not inclined to resort to perineal drainage.

Now the operation of suprapubic prostatectomy has been given a very black eye by one of the speakers, who claims for it a terrible death rate. This may have been true of the earlier operations done by the crude technic of McGill's first operation, with its large incision, but is by no means true of the operation which has been described in the papers of Drs. Fuller and Guiteras, and certainly not in my own operations. In many prostatectomies I have lost no patients as a direct result of the operation. One man died the next morning after operation from a pre-existing uremia, and one died in two weeks from a continuation of suppurative cystitis and nephritis due to long previous neglect. So far, I have not encountered a dangerous hemorrhage or one which would induce me to pack the bladder, as has been advised by some, and although I have removed glands larger than my fist, as I have previously described, I have not a single death that can be fairly attributed to the operation. It is not the very large glands that always give the trouble. A gland no larger than an English walnut may completely obstruct, be easily removed, and the patient quickly cured.

My second last patient was 80 years of age and made a magnificent recovery, and a year ago I operated on a man in his 81st year, who also recovered. The day on which I expected to take the train for the Association meeting I received a telephone call requesting me to operate on a case of prostatic obstruction which would be brought the next morning. I mention this case to show the extreme conditions we sometimes find. The man lived seven miles from a physician, who was called without knowing what kind of a case he would find, but the urinary retention was complete. He first tried a rubber catheter without success, and then after nearly half an hour's work, with a metal catheter from his pocket-case, succeeded in emptying the bladder. In the week which followed two other physicians took turns in relieving the man from time to time in the same way. When he was brought to me his scrotum was black with extravasated blood and swollen to about four times its natural size. The bladder could no longer be entered, but a little bloody urine could be drawn from time to time from the prevesical space. At the operation when the incision was made extravasated urine was found outside of the bladder. When the prostate was enucleated there was a clot of black blood an inch and a half in diameter in the tissues under the gland. This man was 72 years of age and a telegram received from my assistant this morning informs me that he is doing well. The profession owes a debt of gratitude to Doctors Fuller, Guiteras, and Syms, for the original work they have done in developing satisfactory methods for the relief of this serious malady.

Dr. Frank Warner, Columbus, Ohio—It has struck me that operative procedures should be employed earlier in the most of these cases. The inclination, it seems to me, is to let the operation for the relief of hypertrophy of the prostate go until it becomes an operation of last resort. If we do not operate before a man is 80 years old, he has suffered from that enlarged prostate many years. Instead of temporizing with this and that method, if we get at it a little earlier and try to avert some of the difficulties that follow, the operation of prostatectomy will receive many more advocates. Instead of waiting until changes have been produced in the bladder and kidneys that render the operation so dangerous, anticipate by an earlier operation. As the gentleman preceding me stated, one of his cases died the following day from uremia. Another case died from some other changes that had already occurred in the kidneys. It only goes to emphasize the fact that if we are going to spend so much time in developing the method to be employed, we want to spend some time in the consideration or give some considerable thought to the question of the time to operate. I do not mean to advocate operating early in every case of hypertrophied prostate. We can not know what ones are going to give great or little trouble. But when a case has proceeded far enough to no longer readily yield its disagreeable symptoms to systematic catherization and bladder irrigation, then is the time to come in with our operation before the extensive pathologic changes have occurred in the urinary apparatus that will render the operation unsuccessful. After these changes have once occurred about the bladder and in the kidneys and the patient has reached a considerable age, it seems to me, it is then better surgery not to attempt the radical operation of prostatectomy, but rather depend upon the drainage of the bladder by a prostatotomy and secure what relief we can in that way rather than in performing the radical operation.

Dr. E. W. Andrews, Chicago—Dr. Fuller has informed us that the Bottini operation is easy, and this is exactly the mistake that those who practice the operation have made. Instead of being easy, I consider the Bottini operation one of the most difficult in surgery. My own experience has been somewhat considerable and disappointing. After Dr. Willie Meyer brought into view very forcibly in his paper the good results of Freudenberg I took it up early and used it 17 times. I am very sorry to say that in this number I had 1 death; that I had only 3 cures, these being rather brilliant and prompt cures, and all the other cases range from complete failure to slight improvement and in some cases with improvement temporarily. I advise cystoscopic inspection of the bladder preceding the Bottini operation, the application of the method only to a limited number of cases, in which we have a circle or collar, which can be divided or in the other cases in which there is rather an abruptly pointing or pedunculated prominence to the right, left or middle. Limited to these selected cases it may give better results in the future. One of my own successful cases developed a somewhat large calculus, the core of which, when I removed it three months later, proved to have been constituted by a slough thrown off from the cautery incision. I should be interested to know whether these have occurred in the practice of others.

Prostatectomy by the median incision in the perineum I consider the coming method. However, as to quick operating, while desirable, we must remember that as in the case of the rectum and other operations requiring the lithotomy position, a very complete anesthesia is essential. We can not hold the patient partly anesthetized in position, and consequently begin early with our incision, as one of the speakers has suggested; working on the perineum before profound anesthesia is attained is rather impracticable. The muscles must be relaxed. Dr. Sym's apparatus is certainly an admirable one, and this leads me to speak of an instrument, the invention of Dr. A. H. Ferguson, which I have found useful. This is a prostatic retractor, accomplishing the same purpose that Dr. Sym's admirable and ingenious apparatus accomplishes in a different manner. The instrument is a urethral staff, inserted like the old-fashioned perineal lithotomy staff. The lower end of this staff would be spoon-shaped, except that it is in reality a hollow band wire-loop. The circumference of the loop here has a measure given in French, say number 25. The introduction of this loop is per urethram, as in lithotomy. Having brought it into the bladder, it is then reversed just as we reverse the Bottini instrument before making the cut. The assistant, holding this loop and elevating it, presses the prostate downward against the peritoneum. We accomplish two things: not only does it press the prostate downward toward

the peritoneum, but on the retraction of tissues surrounding it it restricts the hemorrhage, which, in spite of the statement of the last speaker, may be considerable. We get practically none, or little, until the moment of removal of the instrument at the close of operation.

I agree entirely about the value of narrow incision, for the reason that it diminishes the area from which absorption takes place. I have entirely quit using such an incision as the so-called Zuckerkandl incision for prostatectomy. The horse-shoe incision has the disadvantage that it is too much surgery for these old men; it cuts too much muscle, exposes too much tissue, causing urinary absorption and infection and it is from this source as much as from the suppression of kidney function that we get the uremic poisoning that usually carries off these old men. A small median incision, as described by the first speaker, gives ample room and even with the larger incision we can not see the prostate. When you have made the incision and enucleated your prostate, you have, as a rule, cleared the two lateral lobes with the right forefinger, so that they hang free; and about the last thing you do, I think Dr. Fuller said the second thing you do, is to clear the small middle lobe. As you clear the middle lobe and enucleate, you nearly always get into this sulcus [illustrating] between the middle and lateral lobes and hence you will open the bladder; but you open the bladder not through the membranous urethra, but through the prostatic urethra. If you open the membranous urethra it is pretty sure to be torn, and is less favorable than to drain the bladder.

DR. G. MACGOWAN, Los Angeles—The paper on the skiagraphs of renal calculi is intensely interesting to one who has paid attention to bladder and urethral surgery, for it is a new method placed into our hands, presumably, to be used by all with equal success. We certainly should have in it an agent which would give us better diagnostic results than we have been able to get heretofore. The gentlemen say that they have introduced these leaden bougies through a Brenner cystoscope. Most of those who have used a Brenner cystoscope believe that, for the purpose of viewing the bladder base, it is the best cystoscope that exists, but for the purpose of catheterizing the ureters, it has been one of the poorest of cystoscopes. From my personal experience, and, I believe, from the personal experience of most of the individuals who have devoted time and attention to this specialty of genito-urinary surgery, the catheterization of the ureter by the electric cystoscope, if the ureter be a healthy one, is an exceedingly difficult matter. In the hands of those who use the cystoscope every day, or a number of times a week, if a ureter is enlarged, if you have a gaping ureter, it is not a difficult thing, with a modified Casper, or with the Nitze-Albarren, to catheterize it, with fair ease. I have yet to know of any man except Casper, or one of his pupils, who has been able to claim to catheterize normal ureters rapidly. I saw Young do it in Baltimore, the other day, with the modified Casper cystoscope, on a neurasthenic, who held perfectly still while he did it. Most of us will not be able to use these sounds, and also will not be able to have at our command a person who is competent to take excellent skiagraphic pictures.

I think we all owe to Dr. Guiteras a debt of great gratitude for the most interesting manner in which he presented to us the methods of treating enlarged prostates—I mean prostatectomy and the prostatotomy of Bottini. I say prostatectomy first, because it is my rule to advise my patients, whenever they come to me requiring such relief, to submit themselves to a prostatectomy. If they decline to do so, I advise them to permit a prostatotomy. Once in a while I advise prostatotomy first. I have operated on about fifty old men by prostatotomy and prostatectomy. These men varied in ages from 65 to 81 years; only one was younger, and he was 63. The results have not been perfect, nor can they be, with either method. All you have to do is to take out the bladder of one of these individuals, open it and examine it, and you will see the utter impossibility of the skill of man, under any circumstances, to give such a man a perfect bladder again.

Dr. Fuller and Dr. Syms spoke about obtaining perfect results. This is not my usual experience, but it is wonderful how, after a developed obstruction to the outflow of urine is removed, the apparently atrophied bladders will regain contractility, and the apparently fibroid bladders will expand gradually to useful proportions. In most of the cases of prostatectomy that I have done, I have used Dr. Fuller's method, and I believe, in the large majority of cases of difficult prostatectomies, that it is the only method that is available. You may make your small incision through the perineum, and use the admirable methods described of pulling down the prostate, with success, in thin men with shallow perineums. But if you have a stout man, with a deep perineum, you may insert one finger into the rectum to pull down the prostate and endeavor to work the index finger of the other hand into the narrow space made from the perineal wound, usually through the urethra, into the capsule of the prostate, but you will find that you can not remove a large middle lobe, or an obstructing lateral lobe, projecting well into the bladder, by this method. True, you can pull away, and take out, small pieces of this prostate through the perineum. What does an enlarged prostate look like upon section, in the majority of cases? It looks like a geological specimen known as pudding stone; a matrix filled with nodules of various sizes. The secreting glands, unevenly enlarged, lie embedded in their stroma of fibrous and muscular tissues. You can not usually tell exactly which special lump is the cause of the urinary obstruction. You have to take them all out if you wish to make a certain cure.

A number of years ago I operated upon a gentleman, who was, at one time, the most distinguished orthopedic surgeon in America. I removed from him a prostate as large as a fist, in a number of pieces. I thought I had it all. He made a good recovery. Six months afterwards he died of other troubles. He had instructed me to examine his bladder, prostate and kidneys, postmortem. I did so, and found the left kidney very much atrophied, while the other was nearly destroyed by the pressure of a stone almost as large as a duck's egg. One little glandular enlargement, left in the prostatic stroma at the time of the operation, had grown to be larger than a pigeon's egg. This was intravesical, but, if it had been intra-urethral, he would have had a return of his urinary obstruction.

When a man's leg is broken, and you let him out of bed for exercise and give him a pair of crutches, would he not be extremely foolish to throw away one of his crutches and hobble on the other? That is exactly the position we are in, we surgeons, with regard to operating enlarged prostates. You have, on the one hand, a most excellent method without the knife, given to us by Bottini. You have, on the other hand, a most beautiful and absolutely surgical method of removal, given by, it matters not whom. Because a man can not or will not, or his relatives will not allow him to submit to a prostatectomy, do not refuse him the alternative of a prostatotomy.

What matters it if after a Bottini he has an ounce, or two, or three ounces of residual urine, where he previously had ten, fifty, or even two quarts, as we have seen them have. Is not the cure relatively a good one?

Take up one of these bladders with its wall thickened by chronic cystitis, or fibroid degeneration, enlarged, or contracted—could you hope for a perfect cure? You would not get it if you did. But if, during the remaining years of these old men's lives, you can reduce the disturbance of their nightly rest by lessening the necessity for urinating by five, ten, or twenty times; or, if you only give them extra ease in using the catheter, you have done these men great good.

I want to assure Dr. Fuller that my experience as a dermatologist taught me, years ago, that the scars made by the galvanic current are of two kinds; if you use the positive pole for electrolysis, you will get a contracting scar that is hard, dense, unyielding, deformative. If you use the negative pole you will get smooth scars, flexible, soft, which do not deform—my face is full of them. The burns produced by galvanocautery do not deform, are smooth and flexible. I have in my collection of bladders those of two men operated upon by me by the Bottini method. They have beautiful channels in the

bottoms of their urethræ. If you did not know, you certainly could not pick out what portion of the bladder neck the Bottini incisor had burned through by any contracted or hardened condition of the scar. They are perfectly flexible. His fears upon this point are without foundation in fact, and he can rest assured that the Bottini can be used without that fancied danger.

I wish to pay one little tribute to Dr. Greene's paper. Ultzmann used to teach us in Vienna, that the boy who had gonorrhea and, as a sequel, had an acute prostatitis, which became chronic, lasting for six months, or, for one, two, or three years, was certain not to have an enlarged prostate when he grew old. As I have grown older, I have doubted the exactitude of his observations in these cases. The argument Dr. Greene presents to us in these pictures, is an argument from "after before." I have never seen a prostate in chronic obstructive prostatitis free from inflammation. These prostates have all been inflammatory, and if you will but think about the preceding and accompanying evils of an enlarged prostate, and also of the instrumentation to which these urethras have been subjected, you will readily see that the evidences presented here are worth very little.

With Dr. Fuller's great skill he makes his operation appear too easy, for it does not seem difficult to him. It is not an easy operation. In some of your patients the hemorrhage is extreme; they bleed so that you wish you had never touched them. They bleed until it makes your hair rise. Then others have prostates that you can not peel out and you would be thankful to have a better rongeur than those we use at the present time, to bite our way through them.

Dr. J. E. Allaben, Rockford, Ill.—An old man, 77 years of age, who had suffered from prostatic trouble for ten years, is compelled to use the catheter most of the time. About eight months ago he had complete retention of urine, which had existed for three days when I was called in consultation. Numerous unsuccessful attempts had been made to pass a catheter, and I also failed in an attempt under anesthesia. I did a suprapubic cystotomy, relieving the bladder of several quarts of urine mixed with pus. Recovery was rapid. Would the gentlemen under these conditions recommend either immediate prostatectomy or the operation at a later date when the patient is quite comfortable at the present time, save the slight inconvenience incurred by the wearing of a tube in the suprapubic wound which drains into a rubber urinal worn upon the person? The patient is able to be about and attend to business better than for ten years.

Dr. R. Guiteras, in reply—I would like to answer the Doctor's question regarding the case of prostatic hypertrophy. I think in cases in which a patient has acute attack of retention, and a large amount of urine is present, that the bladder should never be emptied at one time as would result in the case of an operation. If a catheter can be passed we should never draw off more than a pint of urine at the first seance. If we can not pass a catheter after the use of morphin, rest, hot baths, etc., we should aspirate suprapubically, not drawing off more than one pint the first time, as the withdrawal of 18 ounces has caused hematuria, and that of 22 ounces has caused suppression of urine due to acute congestion of the kidneys. If the kidneys are damaged medically or surgically any interference with the genito-urinary tract is likely to cause this renal congestion, as the kidneys can not work as they should. They can not eliminate what they ought, that is, the necessary amount of urea, and uremia and death may follow. Therefore, first relieve the retention, either by catheter or aspiration. Aspirate several times if necessary, then always accustom the patient to the catheter before performing such a radical operation as prostatectomy. Improve the condition of the bladder as much as possible by catheterization and local treatment.

Dr. MacGowan is certainly right. Neither after a prostatectomy or a prostatotomy can one have the bladder which we find in a 21-year old man, although it is wonderful to note how much tone is regained in bladders in which we have seen before the operation by the cystoscope numerous trabeculæ and diverticuli, accompanied by a chronic cystitis, and to think that these bladders really regain tone after an operation, and that the patients have control of them!

I would speak one word in favor of the Bottini operation. Of course, I believe the enucleation of the prostate, prostatectomy, is the coming operation, and that it is in the same position to-day hysterectomy was a number of years ago, and, gentlemen, working along the same lines in which we are now engaged, we will probably some day or other formulate an operation which can be performed with ease, and without much danger to the patient, and which will give good results. This I feel sure of.

The Bottini method does seem to-day a crude and unscientific one, yet the results in certain cases are good. I know this from my own operations, and I have a record of 24 with careful histories and no deaths. I have a number of patients operated upon two years ago, and all but three were relieved. I do not say that they were cured. Two of the three still complain of a constant burning sensation, an ardor urinæ, although their residual urine has been diminished to one-half an ounce. In the other case the patient still suffers from frequency, although the residual urine has decreased from 9 ounces to one-half an ounce. There was another more recent case which was a very remarkable one, as the man had led a catheter life for four years with complete retention and after the operation had only 4 ounces of residual urine.

To illustrate the function of the genito-urinary organs, I mention another case of a man with 5 ounces of residual urine before the operation. Two years after it he said he was perfectly well with absolutely no symptoms. He said he felt as though he had never been troubled with his prostate before, and notwithstanding the fact that the cautery blade had traveled through his prostate in three different places and he was 65 years of age, he still had control of his general functions and came to me suffering from a venereal trouble, saying that he was in prime condition.

One word more about prostatectomy. We can not always enucleate the prostate. Of this I am sure. Some years ago a patient was sent to me for a prostatectomy, but I did not consider his condition sufficiently good to warrant an operation. I felt that he would die, and planned after his death to have an autopsy and remove his prostate. As soon as he died I tried to remove it, but I could only tear it away in little pieces, and could not perform an enucleation. In other words, the enucleating finger could not be made to sweep around the lobes between them and the capsule and shell them out. It must be remembered in speaking of prostates that they grow in the line of least resistance. The capsule is very dense in these cases of prostatic hypertrophy and it is very much thickened. I have seen capsules taken from cases postmortem which were in some places one-half an inch in thickness. Therefore, we can not always tell by rectal touch alone the shape of the prostate. We must be governed as well by the amount of the impediment in the prostatic urethra, by the length of the canal, and the amount of residual urine. We must bear in mind that the gland in undergoing enlargement and working along the line of least resistance tends to protrude, as a rule, not into the bladder as much as it does upward and backward into the urethra and the bladder.

Dr. E. Fuller, in reply—Everyone who has much experience with prostatic surgery will have his individual peculiarities and preferences in operating. In some special instances the perineal route to accomplish the removal of prostatic obstruction is the preferable one. Many times, however, it is not. By the suprapubic route one can always accomplish the removal of the prostatic obstruction. This can not always be done by the perineal route. Dr. Syms, in his paper, illustrates this point for one of his perineal cases failed because he was unable to effect the removal of the obstruction. One can not always enucleate a prostatic obstruction. Sometimes one has to use cutting forceps to effect its removal and very rarely the obstructing mass may be too fibrous and firm even for forceps, in which rare cases Jessup's prostatic scissors may be necessary. Undue hardness and adherency may indicate scirrhous cancer of the part and when such cases are encountered it is

always well to have an histological examination made of the tissues removed.

Dr. Greene's paper was of interest. I do not, however, feel that his conclusions have any support as far as my clinical observations are concerned. In fact, I am firmly of the opinion that prostatic hypertrophy is not in the least dependent for its origin on a preceding gonorrhea. I have often brought to notice the fact that inflammatory tumefactions involving the fibrous tissues about the seminal vesicles and extending into the fibrous capsule of the prostate—the source of which inflammations is the seminal vesicles—are frequently mistaken for prostatic hypertrophy. In the production of these inflammatory lesions the gonococcus, of course, plays an important rôle. There is no evidence of an inflammatory process in the histology of prostatic hypertrophy such as affects elderly men. In fact, Dr. MacGowan has just called attention to the theory that gonorrhea protects against a subsequent senile hypertrophy of the prostate. Whether it does or not I do not know further than that it is a fact that very many sufferers from prostatic hypertrophy seem to be from among those who have led exemplary lives. Another strong point in favor of the fact that gonorrhea has nothing to do with the causation of prostatic hypertrophy lies in the fact: the inhabitants of India, China and Japan seem to be wholly or certainly in very great measure free from that complaint, while gonorrhea is as prevalent among them as it is among the races prone to senile disease of the prostate.

The apparatus shown by Dr. Dawbarn is certainly ingenious. I do not, however, require his apparatus to guard against "wet bed" after my suprapubic cystotomies, since I so close the wound against the drainage tube that no leakage takes place until such time as the tube is permanently removed to allow the closure of the incision. Then, of course, under any circumstances there will be temporary wetness, which requires the wearing of an absorbent pad.

Dr. Andrews thinks that the Bottini operation is not easy, because, as far as I can judge, he has obtained only three good results out of seventeen cases. I do not see that goes to show that the operation is not easy, for I feel sure that Dr. Andrews operated skilfully in all his cases and did as well as anyone could with the Bottini operation. It simply shows the point I made in my paper, to-wit: how few cases are suited to the Bottini operation.

Dr. MacGowan has laid great stress on the vesical lesions, existing many times in the bladders of those who have suffered long from prostatic obstruction and from this argues that even though the obstruction be removed the function of the bladder must remain to a large degree crippled. This is one of the old arguments against prostatectomy. Sir Henry Thompson and Guyon formerly taught that a bladder which had once lost its expulsive force owing to prostatic obstruction would never regain it and that accordingly the removal of the obstruction would do little good. This theory has been shown by clinical experience to be entirely fallacious and so are Dr. MacGowan's fears regarding the recovery of the vesical function and the persistency of vesical lesions. If a prostatectomy is thoroughly and properly done, that is, if all the prostatic obstruction is removed and then if the bladder through the maintenance of artificial drainage is kept at complete rest for four weeks or thereabout, perfect repair will take place in the lesions which have resulted from the obstruction and the bladder on the healing of the drainage and incisions will be able to empty itself naturally. I never had but one case where after prostatectomy the bladder was not able to empty itself. In that instance, owing to the tubercular pericystitis, a disease entirely independent of the prostatic hypertrophy, the walls of the bladder were so bound down by adhesions that they could not contract. Sometimes a patient may dribble a little after the operation, losing some urine on active exercise, but this is usually temporary.

Dr. MacGowan also advanced the theory that in the performance of the Bottini operation if the negative pole of the battery were used for cauterization a less scar would result. Desnos, some years ago, in his experiments on dogs' urethræ disproved this assertion. He found that very severe strictures followed the use of electrical cauterization of the part and that the use of the positive or negative current made no difference.

DR. J. RILUS EASTMAN, in reply—I believe that when Dr. Greene assumes that inflammation is an important etiological factor in prostatic hypertrophy, he is not far from the truth. In the microscopic examination of a considerable number of prostates in Virchow's Institute for the study of the corpora amylacea, I was struck with the great frequency with which the cardinal signs of inflammation appeared in the prostatic tissues. It was developed that the corpora amylacea themselves are formed by the desquamation of spheres of epithelium from the walls of the acini of the prostate gland by subsequent amyloid degeneration of these cells. These prostates were taken from persons of all ages, from childhood to old age, and in all these cases desquamation of acinus epithelium had taken place to a greater or lesser degree. Not only that, but there was almost constant infiltration of the stroma by leucocytes—fibroblasts and young connective tissue cells and fibers—indicating that interstitial inflammation, as well as parenchymatous inflammation existed. It is not difficult to assume, inasmuch as these inflammatory conditions are commonly present, that prostatic enlargement is in some way associated with them. I predict that time and investigation will develop that inflammation is a very important etiologic factor in prostatic hypertrophy.

DR. R. H. GREENE, in reply—I did not expect to be believed when I advanced the view that prostatic hypertrophy was due to inflammation often probably of gonorrheal origin. It is not a popular view. I met a very eminent man yesterday, a member of this Association. I suggested to him that it might be possible that prostatic hypertrophy was due to a continuation of an old inflammation in the posterior urethra. He said: "Oh, no; I am threatened with prostatic hypertrophy myself." It is not a popular view and it will be a long time before it becomes so, but I believe it is the true one.

Dr. MacGowan says that of course we have some inflammation in these cases from the necessary passage of sounds and catheters. I would reply that the text-books on histology and lecturers on the subject have, as the result of autopsical evidence through a wrong interpretation of the evidence, taught that prostatic hypertrophy was not an inflammatory condition, but that prostatic hypertrophy was either a simple adenoma, that is, an increase of the glandular tissue, or an increase of the muscular tissue, or a mixture of both. It is, however, entirely an inflammatory condition, judging from the evidence of the sections furnished by me, with an atrophy of the normal constituents of the gland, and not a local inflammation superimposed on a tumor, which is his view of the condition.

Dr. Fuller says that the inflammation is outside of the prostate in many cases. I believe it. That is why you can not tell by feeling through the rectum whether the prostate is enlarged or not on account of a similar condition to the one he mentions going on frequently outside; but his views concerning that condition have no relation to my investigations, but these specimens I have shown are sections through the prostate and show an inflammatory condition in all of them of various types, and have nothing to do with inflammations outside the prostate. If my theories as to the nature of the hypertrophy are correct, the methods of treatment would apparently be two: one to treat chronic posterior urethritis long and persistently and to keep patients with chronic urethritis under observation for a considerable length of time, and to examine them from time to time after active treatment had ceased; the other is in those cases in whom insufficiency of the bladder has taken place and the residual urine causes trouble to operate and remove tissue enough, to overcome the obstruction and in a manner not to cause the least formation of cicatrical tissue. For these purposes neither the Bottini operation nor the operation for complete enucleation seem indicated. You have in the West, a man in St. Louis, who has done more operations on the prostate, I believe, than any other man in the United States; his method of operating through the posterior urethra with enucleating just about what is necessary, is apparently

attended with a very small death rate. I refer to Dr. John P. Brison, of St. Louis.

Dr. Parker Syms, in reply—I would urge the importance of one thing; if operation is to be done for the relief of prostatic obstruction it should be done early. When physicians and the public understand this and act upon their knowledge a great change will be wrought, for the mortality will be as nothing compared with that of the present time.

Concerning the Bottini operation, I am glad to state my views emphatically. I believe it to be an absolutely unsurgical and unscientific procedure. Years ago it was demonstrated and acknowledged by the profession that internal urethrotomy should not be performed deeper than the pendulous portion of the urethra. Whenever urethrotomy is necessary beyond that point, it should be done by external incision so that drainage may render it safe. This is acknowledged and accepted by the profession. The Bottini operation leaves a wound at the neck of a bladder which is full of infective urine. It is certainly a dangerous procedure. It is an incomplete operation, and I think it will be seen so to be when cases so operated upon have been observed more fully.

I would like to say concerning the failure to remove the prostate in my second case, to which Dr. Fuller has referred, that it was at a time before I had invented my retractor, and it was partly on account of this failure that I did devise the instrument. I believe to-day that every hypertrophied prostate can be removed through a simple median incision in the perineum.

Years ago I learned that when a statement was made by men to the effect that they were able to do things which I thought impossible, not to boldly assert that these things could not be done, for it has been my happy experience in watching the advance of progressive surgery, to find the impossibilities of yesterday become the possibilities of to-day. I think it is proper when one realizes his inability to perform a certain act, to say, "I can not do it," not to say "it can not be done," for there may be found someone who is able to accomplish it.

Concerning the choice of method of prostatectomy, I must say that I think a simple, median perineal wound—which is all that is left after operation as done by the method I have described above—is a far simpler and safer procedure than is any form of suprapubic cystotomy. The drainage is along the line of gravitation and is complete, the wound is a simple one and not large.

The patients are fairly comfortable and recover promptly. I have had mine sitting up at periods varying from the fifth to the tenth day. In two patients, as I have stated, there has been temporary dribbling after healing, but this has been owing to the fact that I made an unduly large cleft through the prostatic urethra. I am not sure to-day whether this is absolutely necessary in some cases or not, but I believe it is not necessary. I think it may be avoided by making the opening in the membranous urethra not too far back. In my last case I was careful to avoid this and was careful to separate the bladder from the prostate before I began the final enucleation. In that patient I removed the tube from the bladder on the fourth day, when I removed the packing; he had complete control of his bladder at once and made a most speedy recovery. That case, when I first saw him, had 52 ounces of very foul urine in the bladder. I did not operate nor empty the bladder at once but I succeeded with great difficulty in introducing a catheter and gradually emptying the bladder and slightly reducing its capacity.

Regarding the final functions of these bladders, I think it may be truly said that we can never restore them to histological perfection, but from the reports of the operators who have done the best work in this line, I think it can be said that these bladders do recover function fully. A bladder that is contracted may be dilated; a bladder that is dilated may be reduced in size. Certainly in my experience the patients have regained their functions so far that they have been able to hold their urine from four to six hours, holding from six to ten ounces, and have been able to empty their bladders, showing practically no residual urine.

THE TREATMENT OF PNEUMONIA.*

DE LANCEY ROCHESTER, M.D.

ASSOCIATE PROFESSOR OF MEDICINE, UNIVERSITY OF BUFFALO.

BUFFALO, N. Y.

In order to formulate a rational plan of treatment for a given disease it is necessary to recognize the nature of the disease, its course and mode of termination when recovery takes place, and its course and mode of termination when death occurs; it is also necessary to be able to recognize by symptoms and physical signs the changes that are occurring in the organs and tissues of the body during the course of the disease and to know the prognostic value of such changes when recognized.

Pneumonia is an acute infectious disease manifesting itself as a general toxemia, with a local disturbance in the lung passing through the clinically recognizable states of congestion, hepatization and resolution or disintegration.

A brief review of the clinical course of a favorable case shows us the initial chill; the high temperature; the increased frequency of respiration; the pulse of moderate frequency, full volume, high tension and normal rhythm; the coated tongue; the anorexia; the sluggish liver and inactive bowel; a kidney not functioning properly; the diminished excretion of chlorids; the presence in the urine of albumin, and usually casts; the more or less pronounced nervous symptoms; the cough; the rusty sputum; the dry hot skin; the flushed face of slightly dusky hue, and the leucocytosis. For a week or ten days these symptoms persist, the most important change occurring in the increasing frequency of respiration, and loss of the tension and sometimes change in rhythm of the pulse.

At the end of this period there occurs a profuse sweat, the temperature falls, the respiration becomes less frequent, the pulse improves in rhythm, the patient falls into a quiet sleep and awakens refreshed and well. If the case does not go on to recovery or dies before the time of the crisis, death occurs either from the intensity of the toxemia or from interference with oxygenation from involvement of too great extent of lung or from some complication.

The chief cause of death in pneumonia, exclusive of complications, is failure of the circulation through degeneration of the myocardium.

Several factors enter into the causation of this myocardial degeneration, namely, the toxemia of the infection acting directly upon the muscle fibers; the same cause active in the general system and producing an increase in the arterial tension throughout the body, thus making harder work for the myocardium of the left heart already suffering from toxemia; the morbid changes in the lung causing obstruction to onflow of the blood from the right heart, thus throwing harder work upon the right myocardium also suffering from the toxemia. The amount of pulmonary involvement would be, of course, a decided factor from this point of view, as well as from that of interference with oxygenation, too great an interference with oxygenation producing death.

Sometimes death occurs from the effect of the toxemia upon the brain-wild maniacal delirium wearing the patient out, or a low, muttering delirium ending in coma and death. Sometimes the kidney bears the

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S. Davis, Jr.

brunt of the attack and uremia is added to the toxemia of the infecting organism.

Occasionally the gastro-intestinal tract is most seriously involved, and there occurs a violent diarrhea or a marked fibrinous inflammation of the lining mucous membrane.

The most common and serious complications of pneumonia from which death may occur are meningitis, pericarditis, endocarditis, nephritis and empyema. These, however, will not be considered in this discussion, which is limited to the treatment of pneumonia.

This review of the course and modes of termination of pneumonia shows that the most serious element in the disease is the toxemia, and next to this in degree of seriousness is the amount of lung involvement existing at any one time in the course of the disease. The first aim of the treatment, then, should be to get rid of toxins. The natural avenues of excretion by which toxins may be carried off are the respiratory, the renal, the gastro-intestinal and the cutaneous. In all cases of pneumonia the lung and the kidney are involved in the morbid process to a greater or less degree, according to the case. It would be obvious folly then to attempt to stimulate either of these tracts to any great excretory activity.

The bowels and the skin remain and nature has pointed out by the profuse sweat that occurs at the time of the crisis the avenue that she chooses for the greater part of the work of excretion. Accordingly, the prime therapeutic measures for relieving the toxemia are opening up of the bowels and skin and keeping them active. For this purpose there should be administered an initial dose of calomel of 0.50 gram followed by a saline laxative. This measure should be repeated during the course of the disease for the same purpose as the first dose and for the further purpose of relieving the distension of the right heart when indications of that condition are present.

To keep the skin active there is nothing more efficacious and less harmful than the proper use of the hot mustard foot bath. This can be given with next to no disturbance of the patient, the tub being put into the bed, with most excellent results so far as sweating is concerned. These baths may be kept up at four-hour intervals throughout the course of the disease. This sweating, in connection with the stimulation to be referred to later, is, in the opinion of the writer, the most important of the general therapeutic measures.

Another measure of value in preventing further bacterial invasion, is the frequent and thorough cleansing of the mouth with a mildly antiseptic solution. I think this a measure of considerable importance, as we know the pneumococcus is present in the mouth in considerable numbers.

While attempting to get rid of toxins by these means, it is important to put and keep the patient in the best possible condition to resist and overcome the toxemia that is present. For this purpose care should be exercised in the selection of a proper diet. This should be fluid and so far as possible should be sterile, so that no new poisons may be introduced. A large amount of pure water should be administered so that there may be plenty of fluid to flush the excretory organs. It is best administered in small amounts at short intervals.

Besides food, stimulation is necessary, and among stimulants strychnin and alcohol are the most useful in pneumonia. Moreover, the administration of them should not be delayed until failing circulation peremptorily calls for them. As soon as the diagnosis is made the strychnin should be begun in doses of 0.002 gram at four to six hour intervals as indicated. The interval may be shortened and the dose increased as symptoms which call for such increase in dose appear. As much as 0.004 gram every two hours may be given hypodermically with the best results.

Next to strychnin, alcohol is our best stimulant. Nevertheless, in some cases it seems to produce decided cerebral disturbance, particularly in those addicted to its abuse. In such cases ammonium carbonate or aromatic spirits of ammonium is a most useful substitute. These drugs are usually well borne by the stomach if combined with liquor ammonii acetatis and administered in mucilage or milk.

The local treatment of the lung is of importance. A careful physical examination of the chest should be made by the physician at every visit. In this way he can tell when congestion is beginning in any part; and vigorous local treatment will in many cases prevent the further progress of the morbid process. As soon as a portion of the lung is shown by physical examination to be in a state of beginning congestion, the prompt and thorough application of leeches, wet cups or dry cups over the part, will often stay the process there; or if it does not stop it entirely, will delay its progress twenty-four or forty-eight hours and give an opportunity for the clearing up of any previously involved portion of lung. My preference is for leeching or wet cupping. If dry cupping is resorted to, it should be very thorough, the skin and subcutaneous tissue rising up in the cup to as great a height as possible and turning blue or purple while there. The cups should be left on for a half hour and the process repeated every four to six hours. I have seen, postmortem, the direct anatomical evidence of the local value of this procedure, when thoroughly done. During the intervals between the applications of the cups the chest should be covered with a light woolen jacket. The poultice jacket should be relegated to the dark ages.

With ice applications I have not produced the relief of congestion desired. If, in spite of these local measures to relieve congestion, the process still persists and we begin to have evidence of over-distension of right heart, such as increasing cyanosis, the pulse losing its tension and becoming small and sometimes irregular, the liver enlarged, the veins pulsating and the area of cardiac dulness increasing chiefly to the right, whether a murmur of tricuspid insufficiency is present or not, prompt relief can usually be obtained by the withdrawal of 8, 10, or 12 ounces of blood from the median vein of the forearm. This procedure may be repeated several times if need be in the course of the disease. The procedure is of value both for its local effect in relieving the right heart distension and also for its general effect in withdrawing a decided amount of toxic material. At this time a little digitalis, given with due regard to its physiologic effect, may be of decided value.

After the withdrawal of blood, and in cases in which heart failure is imminent without evidence of right distension, the subcutaneous injection of normal salt solution has on several occasions proven of inestimable value. The use of the salt solution by rectum has also been of value, but of course does not give the prompt result that the hypodermic administration does. Whether the value of the procedure is dependent upon the restoration of bulk to the blood after the relief to the right heart has been obtained or whether the salt itself is of value, is

worthy of investigation, the fact being established that in three cases that have come under my observation—in one of them three times—the administration of the salt solution certainly had a marvelous effect in averting an evidently impending death.

If more than one lobe is involved the regular administration of pure oxygen gas at stated times, shortening the interval and prolonging the duration of the administration if cyanosis persists or increases, or if the frequency of breathing progresses to dyspnea, has proven of undoubted value in a number of cases.

In case of sleeplessness and restlessness chloralamid, chloral, Dover's powder, morphin and hyoscin hydrobromate are to be recommended in the order named; though with the thorough attention to the relief of toxemia by keeping the bowels and skin active, it is seldom that recourse to hypnotics is necessary.

On the possible complication of pneumonia I do not wish to touch, as that would take me beyond the scope of the subject announced; but I do desire to say that under the eliminative supporting treatment outlined complications are rare.

Before closing I wish to utter a protest against the treatment of pneumonia by large doses of digitalis in the early stages of the disease as irrational and unscientific, being based on a wrong conception of the nature of the disease.

If our conception of the infectious nature of pneumonia is correct, by the time the chill has taken place the disease is established, and any efforts to jugulate the disease by the use of remedies employed to overcome or prevent pulmonary congestion are most certainly misdirected, for preventing the change in the lung—and it is doubtful if the digitalis treatment can accomplish this—certainly will not overcome the toxemia; two of the most serious cases of pneumonia that have come under my observation have had no pulmonary involvement demonstrable by physical signs.

The treatment of pneumonia by the pneumococcus antitoxin is the natural and rational plan from the recognition of the infectious nature of the disease, but so far the attempts to produce a reliable antitoxin serum that will preserve its antitoxic powers have not been entirely successful, and consequently there are very great variations in the reports as to the results obtained by its use. However, improvements are being made and eventually I have no doubt that pneumonia will be put in the same category with diphtheria, which was formerly dreaded and of great mortality, but now, when carefully studied, diagnosed early and properly treated with large doses of antitoxin, shows 100 per cent. of recoveries. Until that time comes, however, we will get our best results by recognizing the essentially toxic nature of the disease and treating it along the eliminative supporting lines here suggested, which may be briefly summarized as follows:

1. The sustaining of the metabolic processes of the individual by the administration of easily digested or predigested foods in small quantities at stated intervals, the administration of large amounts of pure water for eliminative purposes and the administration of oxygen gas by inhalation whenever the absorbing surface of the pulmonary mucosa is involved to such extent as to interfere with proper metabolic oxygenation.

2. Elimination, (a) by the liver and bowel through the vigorous use of calomel and salts: (b) by the skin through sweats induced by external heat: (c) through withdrawal of blood when indicated by right heart distension.

3. Stimulation of heart by strychnin, alcohol or ammonium carbonate, and in suitable cases by the subcutaneous injection of normal salt solution.

4. The local treatment of the lung by leeching, wet cupping or dry cupping as indicated.

As the value of the method of treatment detailed above was questioned at the time of the presentation of the paper, I beg leave to add, in publication, the statistics on which its value rests.

In some of the cases the notes are, unfortunately, decidedly incomplete, even the date of crisis not being mentioned, but enough is present—date, age, diagnosis, complications, treatment and result, to give them the necessary value for this statistical report.

The cases reported are from the service of Dr. Charles G. Stockton in the Buffalo General Hospital, my own service in the Buffalo Hospital of the Sisters of Charity and from my private practice.

Altogether, 168 cases were treated with 17 deaths. This gives a death rate of 10⅛ per cent. This is better than most other methods of treatment, and if the cases that died are analyzed it will be found that four had been sick a week or more before treatment was instituted, and so can not fairly be considered, that two suffered with chronic nephritis, one had asthma and a dilated heart as well as being 89 years of age; that one had typhoid fever as a complication and that two entered the hospital with delirium tremens, no history obtainable as to the length of illness and died in less than 48 hours. If these cases are excluded, as I think they fairly may be, it reduces the number of cases to 158 and the deaths to 7, giving a death rate of 4.43 per cent. better than any other plan of treatment that I have heard of.

Although the number of cases reported is small it covers a period of a little over ten years and includes cases from all walks of life and of all ages, and may therefore, I think, be considered fairly representative.

THE ABORTIVE TREATMENT OF PNEUMONIA.

A PLEA FOR THE USE OF CARDIAC DEPRESSANTS IN THE TREATMENT OF THE CONGESTIVE STAGE OF PNEUMONIA.*

W. L. DICKERSON, M.D.
ST. LOUIS, MO.

In presenting this subject I have nothing new to offer and for this I apologize, but in this day of rapid advancement in medicine we are apt to reach out after the newer remedies and forget the older ones; therefore, I offer this plea for the use of one of the old cardiac depressants which seems to be rapidly giving way to new, and, I believe, less valuable remedies in the treatment of the congestive stage of sthenic types of pneumonia, namely veratrum viride.

That it is applicable to the congestive stage only and that the physician is often called too late to use it, I am perfectly willing to concede. I must admit also that its use really is an abortive treatment and that in the stage of hepatization is worse than useless and may be said to be malpractice.

We must also bear in mind the fact that many cases of pneumonia run through their course without medication and terminate satisfactorily; also that when we apply treatment we are often uncertain whether we have benefited our patient or not. Perhaps he would have gotten along just as well without our aid.

We may apply our abortive treatment and our patient get along admirably, but almost every practitioner, especially of the country, where we so often find cases of pneumonia in the robust, will tell you that he has met cases in which he was certain the patient must have a full-fledged pneumonia, bound to run its course, and yet in three or four days find him looking about over his farm seemingly a perfectly well man. We can only apply our remedies, and if successful, we are happy; if not, who can say but that our patient might have been worse had such treatment not been instituted.

In the congestive stage of pneumonia we must suppose that we have to contend with a condition not unlike an inflammation in other parts. When such inflammation takes place the vessels begin to dilate in the inflamed area, and as their lumen becomes larger the blood is attracted in this direction and soon a much larger amount of blood is accumulated here. The heart becomes somewhat excited and with each stroke increases the amount. Under such conditions it seems that the vessels in other portions of the body are contracted, thus increasing the amount sent to this area and lessening the opportunity to get away from it. A condition of stasis exists—stagnation, if you please. Still, the heart

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. Thomas Hunt Stucky, Leon L. Solomon and N. S Davis, Jr.

with every stroke is adding more blood to the oversupply, and soon the white blood corpuscles begin to migrate and we have our exudate escaping through the weakened walls of these overcrowded vessels. But the process goes on; the excited heart is pumping more blood into the area; the vessels become more dilated, consequently weaker, and the exudate greater.

In what way can we relieve the condition? There seems to be two rational methods of relief: bleeding and the use of cardiac depressants. The use of the coal-tar preparations is common in this stage, but I believe nearly all thinking physicians will agree that it is not rational treatment.

Nancrede proved that blood taken from the venous side of an inflammation produces an increase in the rapidity with lessened force in the circulation in the parts.

Certainly it is reasonable to suppose that a certain amount of blood taken from the vessels will relieve this congestion. It would seem then that our forefathers, when they advocated bleeding, were as rational in their treatment as we are in some of ours; but our knowledge of the disease has taught us that if it must run its course, the patient needs all the blood he has to withstand the strain; therefore, bleeding is now avoided and we look for other measures. On the other hand, our physiologists have taught us that the vessels of the human anatomy when fully dilated are capable of holding more than twice the amount of blood contained therein. Further, it has been demonstrated that the abdominal vessels alone when fully dilated will hold all the blood in the human economy.

Now, if we can in this stage of congestion, by the use of some drug, accomplish in a few hours this dilatation of the vessels, the blood will naturally seek the course offering least resistance. Then the inflamed area is relieved of pressure and stagnation; the exudate ceases to be thrown out, or at least in much less quantity. Have we not then accomplished something in the treatment of this condition? Will we not by limiting the exudate lessen the severity of the attack, perhaps abort? There are three drugs in our armamentarium capable of doing this: Tartar emetic, aconite and veratrum viride.

The first is too depressing to use satisfactorily. To get the effect upon the vasomotor center, tartar emetic must be pushed to such an extent as to produce very unpleasant nausea and sometimes purging; and the depression is so marked that it is best not used.

Aconite, while it answers very well, does not sufficiently paralyze the vasomotor center to widen the blood paths so markedly as does veratrum; nor is it so safe; consequently it must take a second place.

Wood, in speaking of veratrum viride, says: "In full therapeutic doses it lowers the pulse rate both by a direct action upon the muscle (jervin), and by stimulating the inhibitory nerves (veratroidin); it diminishes the force of the heart beat by a direct influence on the cardiac muscle (jervin) and produces a general vasomotor paralysis (jervin)." Butler, in speaking of it, says: "Jervin renders the pulse slower and softer with marked reduction of arterial pressure. This action is due to direct depression of the cardiac muscle, or of the motor ganglia, the dilatation of the arterioles being the result of a depressant effect upon the vasomotor center."

Further; it is safer than either of others named. Veratrum viride then fulfills all the indications. It is efficient; it is safe. By its action we may paralyze the vasomotor center, dilating the blood paths all over the body, and the blood flowing in the way of least resistance; the vessels in the inflamed area are relieved of the pressure and the consequent exudate ceases to be thrown out.

To do this it has seemed best to me to administer the tincture (U.S.P.), which is a 40 per cent. solution, in oft-repeated doses. Norwood's tincture is a 50 per cent., or a saturated solution, and possesses no advantage over the tincture.

From 2 to 5 minims of the tincture is given every thirty minutes to an hour, until the physiological effect is noticed, viz., some nausea, sweating, relaxation of the skin, a reduction of the pulse and temperature. Keep the patient quiet in the recumbent position to avoid excessive nausea, bearing in mind that vomiting in all cases should be avoided if possible. In this there is usually but little difficulty. Small doses of laudanum have been recommended for this purpose, but it is seldom necessary if the above precautions are taken and the remedy is prescribed in peppermint water.

After such reduction in the pulse the remedy may be continued in the same sized dose, but at longer intervals, say from two to four hours, so long as it seems best to control the circulation. Given in this way, beginning within the first few hours after the initial chill, many cases may be aborted, and the patient is back at his business in three or four days.

In those cases in which we fail to abort, or are called too late to do so, it may be administered as suggested, so long as it seems necessary to control the circulation. This is sometimes a very difficult point to decide. Certainly I have not been in the habit of stopping its administration as soon as an exudate is found present, as has been advised by some writers upon the subject. But so long as the pressure is too great, the exudate being thrown out and the pulse angry, I have been satisfied with its results and believe that it lessens the amount of exudate and therefore cuts short the attack.

DISCUSSION ON PAPERS OF DRS. ROCHESTER AND DICKERSON.

Dr. De Lancey Rochester said that he must antagonize the position taken by the author of the last paper. He thought that the treatment of acute pneumonia by the use of aconite, veratrum viride, and tartar emetic, a most irrational treatment. The patient dies from the heart. Now, what does this treatment do? It commences by depressing the heart. If we wish to act upon the peripheral circulation, why not use warm baths and counter-irritation? The patient is suffering from toxins; we are dealing with an infectious disease; why begin with a depressing agent?

Dr. W. L. Dickerson said that it is true that veratrum viride will depress the heart and it was just for this reason that he gave it in acute pneumonia, but only during the congestive stage. If we can prevent excessive congestion and excessive exudation by this agent why not use it? Digitalis increases the congestion by stimulating the vasomotor center, and contracting the arterioles, thereby raising arterial tension. Therefore, it should not be given early in the disease. He does not give his patients veratrum viride after the stage of hepatization has commenced; but if a patient can be seen in the first six to twelve hours, he gives it in small doses as described in his paper and his patients get well. As regards the other treatment, namely, with strychnin and applications to the chest, mustard foot baths, etc., he approved of them when indicated.

Dr. J. F. Spelman, Anaconda, Mont., said that he believed that no man had ever aborted pneumonia. If a patient starts out with acute pneumonia, he has an infectious process which will go through its stages regularly to resolution, or one of the less favorable forms of termination; but it will not be aborted. He approved generally of the treatment in the first paper. There were two points that he would wish to make in regard

to therapeutics. Before speaking about them he would like to explain that in his practice in a mining region he had had unusual opportunities of observing this disease, considerably greater than those of ordinary private practice. From the experience which he had had during the last four years, he had come to the conclusion that medicine does not affect acute pneumonia at all. Apart from acting upon the organs of elimination, which had been spoken of, and a supporting treatment, remedies are of no avail. For the pain, a hypodermic of morphin—one-eighth grain—is perhaps the best. In the general treatment, strychnin, cocain and caffein do good, not because the heart is failing, but because it is going to fail and they prevent it. For the pneumonic process, there is no specific treatment at the present time.

DR. DE LANCEY ROCHESTER said that he wished to explain that the reason he had presented his paper was because he had observed reports in various journals lately which spoke of cutting short acute pneumonia by the use of certain agents. His object was to point out that in this disease we have to deal with toxemia, and that cardiac depressants are out of place. He thought that the reader of the last paper makes a mistake in giving cardiac depressants and in not giving strychnin early enough.

DR. RICHARD C. MOORE, Omaha, Neb., said that no treatment for acute pneumonia could be formulated into a hard and fast rule to apply equally to all cases. We must take into consideration the general condition of the patient, and the attendant circumstances, in selecting the appropriate treatment. While the treatment advocated by Dr. Dickerson would be useful in some cases, to put an alcoholic patient upon such a depressing treatment would be only to hasten the fatal result. On the other hand, to subject a sthenic case to the opposite course of treatment, to fill him up with food and inject strychnia into him, would hardly be in accordance with our views of proper treatment. In such a case, the veratrum viride would give prompt relief; the excited restless patient sinking into a sweet sleep after a few doses. So in cases which start in asthenic and you give him whisky and cardiac stimulants, you have the delirium lessening and he will sink into a quiet sleep. The treatment must, therefore, be appropriate with the stage and condition of the patient. After we get the patient into a more comfortable condition, we can then consider the infectious character of the disease. Some years ago, at the recommendation of Dr. Andrew H. Smith, of New York, he had used the carbonate of creosote in acute pneumonia and he had been surprised to see that he could get the crisis so soon after the administration of this remedy. With regard to local applications, he knew of nothing that would equal the oiled-silk jacket during the acute stage; under this oiled silk he makes a cold-water application, upon absorbent cotton. It is astonishing how much relief is afforded to the patient by the cold water and oiled-silk applications. After taking it off and leaving the house the speaker had known patients to beg the nurse to renew it. This can be accepted as proof that it is of value. He desired to call attention to the usefulness of carbonate of creosote in acute pneumonia, which he thought acted almost like a specific.

THE CHAIRMAN, referring to the increased mortality from acute pneumonia reported by the preceding speaker, said that there had been an epidemic of influenza during the last few months, which may have been the cause of the increased number of cases of pneumonia and increased mortality.

DR. SPELMAN said that there had not been any influenza in his part of the country for the last six months and did not regard his cases of pneumonia as of this type.

THE CHAIRMAN explained that he had asked this question because in many of the communities of the East the mortality from pneumonia had increased greatly, and it had occurred to him that it was due to the fact of the prevalence of influenza at the time.

DR. CASTON said that he lived in a malarial section of the country in Tennessee, where they have malaria in the warm months and the same patients have pneumonia in the winter months. He realized that this disease is generally said to be an infectious disease. He knew that authorities state that it is a self-limited disease. But he could not agree with these gentlemen altogether, because if his experience had taught him anything whatever, it was that pneumonia can be aborted by a good article of veratrum viride. He was firmly convinced of this fact. He had practiced in the country for 19 to 20 years and he had treated a great many cases of pneumonia and he had aborted a great many cases of pneumonia. He had so much confidence in this treatment, based upon his own experience, that he could say, if there is anything he liked to treat it was pneumonia.

DR. MARY K. MCCOY, Duluth, Minn., inquired of the last speaker, how did he know that it was really pneumonia, if the cases got well so soon? How could he know that it would have been pneumonia, if it had not been aborted?

DR. HOFFMAN, St. Paul, said that nearly every medical society that he had attended for the last few years had had a symposium on the treatment of pneumonia. He had observed that nearly every man who had read a paper had given some scheme for saving patients. Now, in spite of all this, it is a deplorable fact that the death rate of pneumonia is increasing in the last few years. Whether it is because our statistics are more correct, or it is because the disease has become more virulent, he did not know, but he thought that it was the general experience that the disease at present is more fatal. But this is no reason for losing faith in the good effects from treatment. He said that the experience of the Doctor from Montana was correct and that the mortality had been greater. When he first went to Montana he had treated his patients and had lost some, but his results were encouraging. It would be just as much a mistake to give depressants to all cases as it would be to give digitalis and strychnia to all cases. He, therefore, approved the recommendation to adopt the treatment to the case.

STRABISMUS; ITS TREATMENT.*

A. EDWARD DAVIS, A.M., M.D.

Professor of Diseases of the Eye in the New York Post-Graduate Medical School and Hospital; Assistant Surgeon in the Manhattan Eye and Ear Hospital, Etc.

NEW YORK CITY.

(Concluded from page 1172.)

RESULTS.

Non-Operative Treatment.—In February, 1900, I reported results of treatment in private practice of 40 cases of convergent strabismus by the non-operative method. In these 40 cases 25 per cent. were cured; that is, secured parallelism, and single binocular vision was obtained in 7.5 per cent. of the cases. While in hospital practice, in 262 cases, where glasses alone were tried, and these not faithfully, only about 5 per cent. of the cases were cured.

Since February, 1900, I have given special attention to the non-operative method of treatment of squint in private practice and at the clinic of Drs. Lewis and Van Fleet, at the Manhattan Eye and Ear Hospital, where all of the squint cases, through the courtesy of Drs. Van Fleet and Lewis, came under my personal care. I have also, during that period, been performing Panas' operation, when any operation was necessary, in my private practice, 11 cases in all. At the clinic, Drs. Roosa, Van Fleet, Meanor and myself have operated by the Panas method on 23 cases. Excluding cases which came but once or twice, or have been lost from observation, there are 83 cases upon which to make a final report as to results of treatment, non-operative and operative. Three of these cases had been operated upon by simple tenotomy some years before coming under my care without

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

securing parallelism. By means of non-operative treatment I gave two of them single binocular vision and one of them binocular vision, and have included them in a separate table to show the benefit of non-operative treatment in securing a perfect result after operative treatment had failed. From observing Table No. 1 it will be seen by the non-operative method of treatment 23 cases, or 28.75 per cent., were cured, that is, secured parallelism. Eleven of the 23 cases, or 13.75 per cent. secured single binocular vision; and 3 cases, or 3.75 per cent., secured binocular vision; 17 cases, or 21.25 per cent., were improved, some a little and some very much; 4 cases, or 5 per cent., were unimproved, but these did not follow treatment as directed; finally 2 cases, or 2.5 per cent., became worse while under treatment. Thirty-four cases, or 42.5 per cent., came to operation, the results of which are shown in Table No. 2.

Thirty-seven of the 46 cases in Table No. 1 had convergent squint and 9 divergent. Hypermetropia was present in 41 of the cases and myopia in 5.

By means of the non-operative treatment alone 28.75 per cent. of the cases were cured, and with further continuance of the treatment 30 per cent. at least should secure parallelism. Priestly Smith,[2] in a series of 200 cases, secured binocular vision of some kind in 28.5 per cent. of the cases by the use of non-operative treatment alone, a very close agreement in results obtained in the cases reported by me.

W. Lang and James Barrett[3] reported a series of 102 cases in which 36.3 per cent. were cured by means of glasses alone, but they counted the cases which had five degrees and less of squint as cures, while I have not done so. I have counted no case as a cure which did not have parallelism, the angle alpha being taken into consideration. Judging from all of the statistics that I have been able to look up, I would say 30 per cent. of all cases of squint may be cured by non-operative treatment alone. Such a result certainly justifies our persistent and careful trial of this method of treatment in every case before resorting to operation.

As valuable as the non-operative treatment is before operative measures are undertaken it is just as valuable, or more so even, in completing a cure after operation. He who operates on a squint and does not follow it up with after-treatment and close observation will fail to make a cure in many cases. While, if the cases are followed up with the non-operative treatment, the cure is often completed.

The younger the patient and the earlier the non-operative treatment is begun the better the results. This point has been shown by all observers who have reported cases, and is a well-established fact.

Of the 34 cases which came to operation 29 cases were convergent and 5 divergent. Hypermetropia was present in 31 cases, 3 of which had divergence; myopia was present in 3 cases, one of which had convergence.

Twenty-six of the cases, or 76.47 per cent., secured parallelism, 11 of which latter cases, or 32.35 per cent., secured single binocular vision, and 2, or 5.88 per cent., binocular vision. Five cases, or 14.70 per cent., had over-effect, and 3 cases, or 8.82 per cent., had under-effect. After two operations on two cases of over-effect, and on one case of under-effect two of these cases secured parallelism, making the percentage as follows: parallelism, 82.36 per cent.; over-effect, 11.76 per cent.; under-effect, 5.88 per cent.

2. Trans. Ophth. Soc. Unit. King., vol. xviii, 1898, pp. 17-47.
3. Ophth. Hospt. Reports (London), 1889.

The remaining cases of over-effect and under-effect are still under observation, and if it becomes necessary will be operated on a second time. In cases of over-effect the second operation is performed upon the opposite muscles to those which were first cut, and in the same way, that is, they are stretched and then cut. In one of the two cases of over-effect that was operated on a second time, advancement of the muscles first cut was performed, but it did not relieve the over-effect; while the other case that had the opposing muscles stretched and cut secured parallelism.

These 34 cases here reported, taken in connection with the 36 cases operated upon by Panas' method and reported by Dr. Roosa eighteen months ago, make 70 cases in all that we have observed sufficiently to report upon. Twelve of the cases that Dr. Roosa reported in 1899 and 1900 have been seen in the last month (May), and the others have been seen now and then since his report. In his first report there was one case of over-effect. The over-effect in this case has diminished until only about five degrees of divergence remains, though ten degrees was present originally. In one case a convergence has resulted, while in two other cases divergence has resulted —one of ten degrees and the other of twenty-five degrees, but this latter case was a complicated one, that is, there was a central opacity of the cornea in the squinting eye. In other words, in two cases the tendency was to divergence, while in two other cases it was towards convergence. Divergence, therefore, after Panas' operation is no more to be feared than convergence, judging by these cases operated upon eighteen months to two years ago.

The results on the whole 70 cases at the present writing are as follows: parallelism, 60 cases, 85.7 per cent.; over-effect, 7 cases, 10 per cent.; under-effect, 3 cases, 4.2 per cent.

[I may say, since compiling the tables of cases for this paper, I have operated on 6 other cases in the clinic, all of which secured parallelism and one single binocular vision. If we add these cases to the 70 here reported the number of cures would be about 87 per cent.]

In these cases it must be remembered that two operations were performed on only 3 cases, the desired effect being obtained by one operation together with non-operative treatment. And it is this very feature of the operation, its effectiveness on one trial, which makes it superior to other operations. To show the value of this operation as to ultimate results it is only necessary to compare it with results obtained by the old methods of simple tenotomies, advancements, etc.

In 1886, Roosa reported a series of 100 cases of convergent strabismus, which he had operated upon, with results obtained, together with the review of the subject of squint. In this paper he said he had been able, after careful search, to find tables comprising a scant 300 cases. Of the 100 cases he operated on parallelism was secured in 79 cases, or just 79 per cent.; convergence remained in 16 per cent.; divergence in 4 per cent., and upward squint in 1 per cent. That is to say, 21 per cent. were failures although he operated on some of the cases two or three times, and stated that in some cases, not included in his tables, he had operated four and five times on a single case. His results in these 100 cases are a fair average as compared with the results obtained by other operators who used the same method. The results obtained by the same operator and his pupils by Panas' method are considerably better, and are secured in the great majority of cases, as observed earlier in this

TABLE 1.—RESULTS OF NON-OPERATIVE TREATMENT IN FORTY-SIX CASES TESTED UNDER A MYDRIATIC.

No.	Date, Name, Age (years).	Diagnosis.	Deg.	Fixation	Duration.	Vision and Refraction.	Treatment.	Results.
1	Jan., 1900, G. L., 3½	Convergence, constant, left	20	False	Since 8 months old.	Objective tests; R. H. 3 D., L. H. 4 D.	Atropin, exclusion pad. glasses, +2.75, R.; +3 50 L.	May, 1901; convergence 10°; has not worn glasses all the time or followed other treatment steadily.
2	March, 1900, M. F., 3½	Conv., const.. some nystag.	20	True	Unknown	Objective tests; H. 1 D. each	Glasses, pad; atropin intolerable.	May, 1901; convergence 5°.
3	Oct., 1900, H. G., 25	Conv., period.	10	"	23 years	R. 20/20w. +1.25 D.; L. 20/20w. +1 50 D. +1.25 C. 105°	Glasses, pad, stereoscope	Single bin. vis. after 2 weeks, which holds May, 1901.
4	Feb, 1901, A. H., 5	Convergence, constant, left	30	"	1 year	Can not read; objective H. 2 D., R. C. H. Astg., L. 1 50 D. 50 C. 75°.	Glasses, atropin, pad.	May 5, 1901; patient gave up all treatment after first week because of illness; squint same as at first, 30°.
5	Jan., 1900, E. P. O. B., 18	Divergence, alternating.	5	"	1 year.	R. 20/50: 20/10w. −.75 D ⊂ −.50 C. 165°, L. 20/50: 20/10 w. −1 D. ⊂ 50 C. 15°.	Glasses, stereoscope	May, 1901; condition unchanged; gave up all treatment after 3 months
6	June, 1900, M. C, 30	Diverg., const left.	15	"	Unknown	R. 20 200:20/40w. −5.50 D. ⊂ −1.50 C. 45°; L. 20/200: 20/50w. −5 50 D. ⊂ 2 50 C. 45°.	Glasses, pad, stereoscope, declined operation.	Slight improvement.
7	June, 1900, J. Y. B., 29	Diverg., alter.	5	"	Unknown	R. 20/15:20/15 +w. +1. D., L. 20/15:20/15 +w. +1. D.	Tonics, stereoscope	One month later single bin. vis.; not seen since.
8	Sept., 1900, H. M., 28	Div., per., alt.	5	"	Unknown	R. 20/20:20/20+w. + 50 C. 90°, L 20/20:20/20+w. +.50 C. 90°	Glasses, tonics, declined opera	Mar., 1901; diverge ce 8°.
9	Oct, 1900, J. C. N., 35	Diverg., const left.	30	"	Since 4 yr. old; operat. 20 yr.	R. 10/200:20/200w. +4 C. 90°, L. 20/40:20/20w. +1.50 D ⊂ +2 C. 90°.	Glasses, declined second opera	Condition unchanged.
10	Dec., 1900, M. A. S., 38	Diverg., alternating.	5	"	Unknown	R. 20/15:20/10w. +.75 D., L. 20/15:20/10w. +.50 D. ⊂ +25 C. 90°.	Glasses, tonics, stereoscope	May, 1901; single bin. vis. all the time; no diplopia as before treatment.

TABLE 3.—RESULTS OF SIMPLE TENOTOMIES COMBINED WITH NON-OPERATIVE TREATMENT IN THREE CASES.

1	Sept., 1900, N. H., 20 .	Convergence constant left.	5	True	Since a baby	R. 20/40:20/20w. +1.50 C. 90° −.50 D., L. 20/200: 20/70w. +2.50 C. 90°.	Had 3 or 4 operations before coming to me; atropia, glasses, pad, stereoscope, bar-reading.	After 5 weeks' treatment single binocular vision, which still holds, May, 1901.
2	Nov., 1900, L. B. L., 30	Convergence constant right.	5	"	27 years. .	R. 20/200:20/30w. +1.50 D. +1 C. 95°, L. 20/70: 20/15w. +.75 D. + 1 C. 90°.	Operation, both eyes, at 8 yr. by another surgeon, glasses; by me, new glasses, pad, stereoscope, bar-reading.	One week, single binocular vision, which holds May 8, 1901; perfect comfort.
3	Sept., 1900, H. F., 17. .	As above...	25	"	15 years. .	R. 20/70:20/20w. +3 D., L. 20/70:20/20w. +3 D . .	Had 2 oper' 3 yr. ago, atropin, pad, glasses	May 14, 1901, eyes parallel; binocular vision.

paper, by one operation, which is certainly a great gain over the method of simple tenotomies, where two, three and as high as five operations are sometimes necessary to complete a cure. Furthermore, the main objections against Panas' operation, over-effect, has not been borne out by the statistics in the 70 cases reported by us and the 250 cases reported by Panas. Panas reports failure in only about 5 per cent. of his cases.

By way of explanation of the greater percentage of failures in the cases reported by Roosa and myself, as compared with the cases reported by Panas, I may say three of our cases were operated upon while the patients' eyes were under the influence of a mydriatic. In each one of these three cases over-effect resulted, due, we believe, to the effect of the mydriatic. Under no circumstances should Panas' operation be performed while the eyes of the patient are under the effect of a mydriatic. Because, immediately following Panas' operation, as a rule, we have a temporary over-effect, and the mydriatic increases it and makes it permanent. It is easy enough to instill a mydriatic if the effect of the operation is not great enough, but it is impossible to get rid of the effect of the mydriatic, for some days at least, when once in. We therefore give word of warning to those who intend to operate after Panas' method not to do so while the patient's eyes are paralyzed with a mydriatic.

In a very few cases a second operation is called for, but with this second operation I believe the percentage of cures (parallelism) will easily be brought up to 95 per cent. in all cases.

Cases Worthy of Special Mention.—Cases Nos. 1 and 8 are remarkable in showing triplopia immediately after operation; the former case being of interest also by reason of the vision in the amblyopic eye increasing from 20/200 to 20/30.

Each of these cases, aged respectively 23 and 25 years, had excessive convergent squint in the left eye from youth, the latter case having but little amblyopia in the squinting eye, while the former had a very decided amblyopia. In each case immediately following the operation there was horizontal triplopia for the near point, and for the distance also for bright objects, as a candle-flame. The second case, No. 8, in the first table, would at times have triplopia, then diplopia and then single binocular vision—all within a few minutes' time. When triplopia was present the image from the right eye was between the two images from the left, and was the brightest of the three, while the extreme right hand image was the faintest of the three. When diplopia was present (in this instance the images from the maculæ were fused, forming one image, while the faint image to the right was from the new-formed macula in the left eye) left image was very bright while the right was very weak.

It required the most favorable surroundings to bring out the triplopia, as a bright light in a dark room. Looking at a white door-knob at twenty feet immediately afterward, he had single binocular vision as shown by prism test.

With the Kroll pictures, the trap and the mouse, for instance (the trap being on the left side of the picture in front of the squinting eye), he saw two traps and the mouse between them. After two days triplopia could not be brought out, and single binocular vision existed from this time on until eight months later when the patient was last seen.

The first case, No. 1, was exactly like the one just recited, except the image from the false macula was weaker. Furthermore, on account of his amblyopia it required a much longer time for him to obtain single binocular vision, taking five weeks to establish it. At first he saw single at five feet and then single binocular vision extended to within one foot of the eyes and as far away as ten feet after a few weeks. Beyond ten feet he had homonymous diplopia, while inside of one foot he had cross diplopia. Five months after the operation the range of single binocular vision was from eight inches to fifteen feet, and he was able with the Kroll pictures to put the mouse in the trap, the flower in the pot, the frog in the pool, etc., but not to fuse the homologous objects of the Kroll pictures, as the two girls or two horses, so as to form one girl or one horse. His vision in the amblyopic eye had increased to 20/50, at this time. One month later the vision in the bad eye increased to 20/40, and single binocular vision existed for all distances beyond six inches. He was able also now to fuse the homologous objects of the Kroll pictures.

A third case somewhat similar to the two cases here reported is one from the hospital clinic where paradoxical diplopia followed operation. E. S., aged 11 years, divergent strabismus, 30 degrees, constant most of the time in the right eye, though occasionally the left eye squinted; duration 10 years.

R. V. 20/70; 20/20 w. —1.50 D.

L. V. 20/40; 20/20 w. —1.00 D.

The treatment consisted in wearing glasses and having Panas' operation performed. Immediately after the operation there was a divergence of ten degrees, but a homonymous diplopia of six degrees. Ten months after operation the patient had single binocular vision both with and without glasses.

The three cases just cited and the two to follow form other links in the chain of positive evidence in favor of amblyopia ex anopsia, but before commenting on them I will cite the two cases in hand of marked amblyopia which were greatly improved by treatment.

A. S. (Case 9 in Table 2), aged 6 years, convergence 25 degrees, constant in the left eye, duration one year, true fixation, R. V. 20/30; L. V. 10/200. Under atropin:

R. V. 20/100; 20/20— w. +3.00 D.

L. V. 10/200; 20/200 w. +3.50 D.

These glasses were ordered and the exclusion pad to be worn one hour three times a day over the right eye; also atropin was instilled twice a day into the eyes for a month at a time with intermissions of a month. After three months the amount of the squint was reduced to fifteen degrees, but could not be further improved with three more months of treatment, making six months of all of non-operative treatment. Panas' operation was now performed. On the following day the eyes were parallel, and on the second day after operation single binocular vision was present for the near point. The exclusion pad was ordered to be worn one hour three times a day on the right eye; three months later single binocular vision existed for all distances with vision 20/20 in each eye with glasses, + 3 D. each. Adduction 13 degrees, abduction 6 degrees, sursumduction, right and left, 3 degrees.

Another case in point, No. 16, Table 2: Ada D., age 38, high myopia, convergence 60 degrees right eye, with false fixation, 10 degrees convergence left eye; duration twelve years. R. V. 3/200 not improved; L. V. 4/200; 20/50 w. —12 D. ⌒ —1.50 C. 180°.

The ophthalmoscope showed 12 diopters of myopia in

each eye, with normal fundi, except for small scleral ring at the disk in each eye. Ordered glasses —10 D. R.; and —10 D. ⊂ —1.50 C. 180 L. Two weeks later Panas' operation was performed; five days later the eyes were parallel. The patient was ordered to wear her glasses all the time and to wear the exclusion pad on the left eye twice a day for an hour. Thirteen months later the patient had single binocular vision with glasses on, and the vision had increased in the amblyopic eye from 3/200 to 20/50, the same as in the good eye.

The two cases of triplopia and the one case of paradoxical diplopia show that a new perceptive center can be formed in the eye by use, while the last case shows that the center of vision, after it is much reduced, can be improved by use. And Roosa, Risley and others have reported cases where the vision was good before squinting and became reduced after squinting, showing that the vision may be reduced by non-use.

I am as firmly convinced that the non-use of an eye may cause weak vision or amblyopia as the non-use of a man's arm causes weak muscles in the arm. Physiologically one is as easily understood as the other. A quotation from Brudenell Carter is pertinent here: "Vision," he says, "like every other nerve function, must be cultivated for the attainment of a high degree of excellence. The visual power of London children is not cultivated by their environment. They see the other side of the street in which they live, and the carts and omnibuses of the thoroughfares. They scarcely ever have the visual attention directed strongly to any object which it is difficult to see or which subtends a visual angle approaching the limits of this ability; and hence the seeing function is never exerted to anything like what should be the extent of its powers."

Three of the patients reported by me in this paper have complained that the sight in the good eye has been made worse by tying the eye up, it taking at least one-half hour to one hour to recover the normal vision after the patch is removed.

Case No. 12, in Table No. 2, is unique because of the great size of angle alpha, which was 20 degrees in each eye, measured very carefully with the perimeter, time and again.

W. H., aged 16, left eye has always turned outward, mother and two sisters have divergent squint when they become tired. The amount of divergence is 25 degrees, exclusive of the angle alpha, but it looks much greater on account of the very large positive angle alpha.

R. V. 20/15; 20/15 + w. +.50 D.

L. V. 20/50; 20/30 + w. +.50 D. ⊂ +.50 C. 75°.

Panas' operation was performed at once because the glasses had a tendency to make the squint worse. The immediate effect of operation was ten degrees of convergence; nine days later the eyes were parallel with single binocular vision for all distances. His wide angle alpha, however, gave him the appearance of having divergent squint, the so-called incongruous squint of Donders, or apparent squint of other writers. Six months later the patient had single binocular vision by all tests, with and without glasses, and was entirely comfortable, although he had not worn his glasses for two months.

So far as my knowledge goes a 20-degree angle alpha is the largest on record. Cases of as high as twelve degrees have been reported, but I knew of none larger until meeting with this one.

Another case worthy of report is the following: J. O. C., aged 12, convergence of the right eye since an infant, constant; amount 45 degrees, true fixation.

R. V. 20/50; 20/30 w. +1.50 D. ⊂ +1.50 C. 90°.

L. V. 20/50; 20/20 w. +2.75 D. ⊂ +.75 C. 90°.

These glasses were ordered together with atropin and the exclusion pad. Five weeks later the eyes were parallel for the distance with five degrees of convergence for the near point. After three months' treatment single binocular vision was present, which is still maintained. This case is remarkable because of the amount of the squint—45 degrees, the age of the patient before treatment was begun—12 years—the duration, twelve years, and for the result.

CONCLUSIONS.

1. That it is desirable that we have a uniform or standard set of tests for the accurate measurements of strabismus.

2. A better understanding of the physiological action of the ocular muscles and of physiology in general, than at present obtains, should be had by those treating and operating on strabismus cases.

3. The amblyopia present in most cases of convergent strabismus is functional and acquired, and not congenital except in rare cases.

4. The non-operative treatment of strabismus—atropin, the exclusion pad, and, in patients old enough, glasses, the stereoscope and bar-reading—should be begun as soon as the squinting is observed; for, it is in the early cases that this form of treatment is capable of doing so much good. By means of it, if the case is taken in time, false fixation and suppression of the image in the squinting eye are prevented, fusion of the images encouraged, and form-perception, that is, true binocular single vision often maintained. Even where one or more of these functions have been lost persistent effort in the non-operative method of treatment frequently restores them.

5. About 30 per cent. of all cases of strabismus may be cured by non-operative treatment alone.

6. Just as soon as the non-operative method of treatment ceases to improve the condition of the squint, it is time to operate. Delay in operating after this is not only useless but harmful, because the habit of suppressing the image in the squinting eye becomes fixed and the amblyopia worse.

7. After the eyes have been operated on, the use of the stereoscope, bar-reading, the pad, glasses, etc., are of the utmost use in completing the cure.

8. Panas' method of operating for strabismus by stretching the muscles before cutting them is to be recommended as safe in execution, quick in results and efficient. It should never be performed while the patients' eyes are under the influence of a mydriatic.

DISCUSSION IN SYMPOSIUM ON STRABISMUS.*

DR. C. M. CULVER, Albany, N. Y.—The English word "cured" has different meanings as used by different persons. With any meaning of it, strabismus is not, generally, cured by operation. We must have the non-operative treatment before an operation, and afterwards in order to be fair to our patients. When I was invited by Dr. Ellett to participate in the discussion of this subject I was asked to discuss Dr. Jackson's paper concerning the non-operative treatment and therefore my notions concerning the matter are correlated with reference to that. The operation for strabismus provides a condition wherein the trouble may be cured; it does not cure it. It is like the operation for talipes in that respect. Gladden has pointed out that because a person is not a total abstainer it is not fair to assume that he is a confirmed drunkard, and

* For the previously published papers on this subject see THE JOURNAL, October 26, pp. 1087-94, and November 2, pp. 1165-72.

because one advocates non-operative treatment of strabismus it does not follow that he is never in favor of the operative treatment. The opportunity that I had to study this question was encountered during eighteen months of study in Dr. George T. Stevens' office. I have not been quite faithful to that training, for I have never done more than five operations on one case of strabismus. The non-operative treatment should consist in whatsoever can induce the eyes to coöperate in securing binocular vision. It seems to me it is very like teaching a child to walk and for this purpose the apparatus Dr. Jackson shows seems to me most commendable.

Dr. F. C. Todd, Minneapolis—In regard to the objections to the non-operative treatment and the reason it can not always be carried out is because of the length of time necessary, and yet it seems to me the patients should be as willing to subject themselves to the non-operative treatment as to the frequent operations recommended by some authorities. There is one important point which Dr. Jackson mentioned which I wish to emphasize and which should always be carried out. I refer to the correction of the entire ametropia in the amblyopic or squinting eye; this can only be done by subjective means. This is often neglected I am sure from the number of such cases I find who are wearing only a spherical correction when a compound glass is required to produce the correct focus. If we may judge from the literature a procedure upon the subject, tenotomy is doubtless performed more often than advancement; yet the latter is steadily gaining ground. The amount which Dr. Clark stated, as secured by a tenotomy, seems to me to vary a great deal under different circumstances. One operator that I have seen work is in the habit of stretching the tendon and tissues after tenotomy and in that way an excessive amount may be corrected. The operation of tucking is one I have been performing in the past two years, and with an instrument which I have devised for the purpose great accuracy can be secured; if extra guy sutures are used a high degree of strabismus may be corrected in one operation. Dr. Davis' results certainly show the benefits of Panas' operation. Stretching of the tendon, as he described it, seems to me at first a radical procedure, but I can see that it is more conservative in its results than tenotomy without stretching, because while more marked at first the tendon being lengthened from the previous stretching necessarily takes its attachment further forward on the globe and thus, as Dr. Davis suggests, the best results are secured with this operation in strabismus of small degree.

Dr. G. C. Savage, Nashville—There are three terms to be used in connection with the muscle study. These terms are: planing, converging and paralleling. The first two terms are always to be applied to the visual axes; the superior and inferior recti plane them, and the internal and external recti govern the converging. The paralleling is done by the obliques, and has no reference whatever to the visual axes, for the lines that are to be parallel are the vertical axes. It is certainly incorrect to speak of paralleling the visual axes in operating for squint. In the study of squint we must investigate from the three standpoints: planing, converging and paralleling, and our operations must be determined accordingly. We must know beforehand whether there is an error in either one of these three directions, and we must see to it that our operations shall result in bringing the visual axes into the same plane, in giving ability to the internal and external recti muscles to do the proper converging in this plane, and to enable the obliques to always parallel the vertical axes of the eyes with the median plane of the head. While sometimes the error is only one of convergence, not infrequently there is also a failure on the part of the muscles to plane the visual axes and to keep the vertical axes parallel. The first operation done for squint was most likely done about one hundred and fifty years ago by a man named Taylor, and while we can not be positive as to the nature of that operation, I am inclined to believe that it was a division of the inferior oblique muscle. If Taylor, who traveled all over Europe straightening crossed eyes, had been honest with himself and mankind, he would not have kept his secret until his death. His operations were all done privately, and no one was allowed to see the eye until after the evidence as to the nature of the operation had entirely disappeared. I have done that operation myself recently with a high degree of satisfaction in a very bad case of squint, complicated by an extraordinary amount of plus-torsioning. I did this operation because I believed that Taylor, the quack, had done the same operation successfully. In my case I had no fear that the ends of the cut muscle would separate sufficiently to allow the great plus-torsioning to be transformed into minus-torsioning.

As to the kind of operation to be done, I have well-defined views in my own mind, and I put these views into practice. I do not follow Landolt in never doing a tenotomy, but always advancing the weak muscle; nor do I follow those who are in the other extreme, who do complete tenotomies, even severing the check ligaments, but do no advancements. I never do a complete tenotomy on a rectus muscle, but in all cases of squint I do a partial tenotomy of the too strong muscle and a shortening or an advancement of the too weak muscle at the same time. In doing the partial tenotomies I do not always divide the central fibers. If there is a torsioning of the eye complicating this squint, then the peripheral fibers in one direction or the other, depending upon the muscle, and the character of the torsioning, should be cut instead of a central tenotomy. In shortening or advancing a muscle we must always take into consideration the presence or absence of torsioning. If there is no complication of this character, then a muscle should be shortened or advanced in direct line of its original action; but if there is a complicating torsioning, the shortening or advancement must be such as to elevate or depress the plane of its action, as might be indicated. Of all the complete tenotomies that have ever been devised Panas' is certainly the safest and the best. By stretching the muscle before dividing the tendon the fibers are more or less paralyzed, and after cutting the tendon there is less retraction than would be if the fibers had not been stretched. Before these fibers have had time to regain their power, which was taken from them by the stretching, the cut tendon has had time to re-attach itself to the globe more advantageously than the attachment would have been if the retraction had been further back.

Dr. E. F. Baker, Mt. Vernon, N. Y.—For nearly twenty years I have been operating upon but very few cases of ordinary convergent squint. I have found that these cases can be otherwise cured more satisfactorily to the patient and to me. In order to follow up these cases and at the same time receive some compensation for it I have proceeded in a line that might be considered unethical. I found that if I charged $100 for the operation they were quite willing to pay it, but when they came back at the end of the year not much better I had to do the second operation without charge and if at the end of another year they were not improved they began to think the money should be returned. Now, I am in the habit of telling them that I am willing to take care of them for a considerable time and do the best I can and I name a sufficient sum to cover it. In this way I have been able to follow up my cases. In a paper read before the state society some years ago (and I quote these figures from memory), I said that of 105 cases managed in this way 85 were cured to the satisfaction of the patient and only 20 came to operation. I have followed the same plan as laid down by Dr. Jackson, and when the case does not do well and the squint is not corrected I always imagine that I have not done my part of the work well. The great trouble is that these patients do not come young enough. I frequently put glasses on patients at the age of 2 or 3 years and if they be made comfortable to the child there is no difficulty in managing the parents. I was somewhat surprised at the remark of one of the readers that cases of alternating squint were the most difficult. Why, I feel like saying always that these cases are curable.

Dr. J. L. Thompson, Indianapolis—Most of our cases come from small towns where everybody knows us and we can not do things as they do in large cities; now I never operate on them until I think and talk it over with them for a year; sometimes they fall, in the meantime, into somebody else's

hands, and I never regret it at all. We must educate not only the public but the profession on this question, and tell physicians particularly what they may expect of operations done in two minutes. We should impress it upon physicians that they should not send these patients expecting immediate operation. I have offended several physicians by telling them that it is too serious a thing to do at the first office visit.

Dr. F. C. Hotz, Chicago—I believe there is no diversity of opinion as to the importance of the non-operative treatment of convergent strabismus in children. Dr. Thompson has struck a very good point in referring to the ignorance of the general practitioner in this regard. They send patients to us and expect an operation to be done in a minute or two and the parents are greatly disappointed when told that before operating a very minute examination is required to determine the advisability of operating. Now, when it comes to operation I wish to endorse fully one point made by Dr. Clark, that in every case of operative treatment we must divide the effect between the two eyes, whether you correct the convergence by tenotomy or advancement, so as to preserve the harmonious action of the muscles.

Now, I wish to say a word in regard to tenotomy which so far seems to have found so little favor with the gentlemen who have expressed their opinions. It is true that very bad results have been seen after tenotomies of the internal recti for convergent strabismus and that in after years we sometimes have been ashamed to see a patient whom we had operated on years before. But is the bad result the fault of the principle upon which the correction by tenotomy is based, or is it the fault of the operator? I think we should not throw overboard an operation which has its good points because many operators, myself included, have had bad results with it. If the convergent strabismus was the consequence of a faulty action of the externus, certainly the advancement of this muscle would always be indicated; but if it is the result of faulty action of the internus it is certainly not rational to leave the faulty muscle alone and produce an abnormal condition in the normal externus. That the internus is at fault originally is, I think, shown by the good results obtained with the non-operative treatment and also by the occurrence of an alternating strabismus. I can not conceive the possibility of an alternating strabismus due to weakness of the external muscle of one eye. In moderate cases of convergent strabismus of say 15 degrees measured by the perimeter—and I measure my cases by the perimeter—I am sure the internal rectus muscles carefully tenotomized to such an extent as to reduce the abnormal part of their converging power, but reserving the full degree of that power necessary to sustain convergence for near work, can be done with impunity. If the strabismus has lasted any length of time other conditions obtain and it is there that correction by simple tenotomy leads to such slipping back of the muscle that it loses so much of its converging power as to bring about the bad effects mentioned. In such cases advancement of the externi is required. I am standing, therefore, in this position, that I do tenotomies for slight conditions, advancement for middle cases, and combine the two in excessive cases. In alternating strabismus the simple tenotomies will do the work perfectly. I was greatly surprised to hear it stated that these cases were the most difficult to relieve by operations; on the contrary, I find them the most favorable for operative or non-operative treatment.

Dr. D. M. Campbell, Detroit, Mich.—The problem of strabismus varies largely with the kind that we have. If we have a converging strabismus the correction brings us problems vastly different from those applicable to post-operative divergent strabismus. In many cases of convergent strabismus it may be possible to correct by tenotomy, but none of us would have the temerity to say that post-operative strabismus would be corrected by a tenotomy of the external rectus. So before we can profitably discuss the question the different kinds of strabismus should be differentiated. Then again, in the complicated varieties, the convergence, associated with turning upward of one eye, presents different problems from the simple strabismus. None of us would expect to correct that by a simple tenotomy of the internal rectus; we must eliminate the complicating features of each case.

Dr. A. B. Hale, Chicago—I did not suppose the non-operative and operative advocates would become separated in the discussion; both methods must always be used together in order to obtain a cure. I have learned one valuable lesson by my experience with the stereoscope, namely, that binocular vision is not necessarily fusion. Binocular vision can be compared to exercises to which we subject a patient and expect him to go through with it so much at a time, while fusion is a condition to which normal eyes are accustomed. I want to ask Dr. Clark what material he uses in his buried sutures.

Dr. William Wilder, Chicago—It seems to me when the operative treatment of strabismus becomes necessary we should consider very carefully the question of whether one muscle is too strong or the opposing muscles too weak. It would be as absurd to cut a weak muscle in the eye as it would be to make a tenotomy in talipes caused by paralysis. That plan of treatment has been discarded in most cases by the orthopedists. If we find that the abductive power of one muscle is at fault we can procced to strengthen it by advancement and in such cases I have been able to obtain excellent results by operating on one eye alone, although in many cases I do divide the operation between the two eyes. There is one point in regard to the technic of advancement that I think should be insisted upon in high degrees of convergence or divergence; it is impossible to correct the deformity without resecting a considerable portion of the tendon and in many of these cases I have secured the best result at the time by having the patient look at a red light for a test at the time of operation. Before the sutures are finally tightened the patient watches the light with a Maddox rod and I tie the stitches one at a time.

Dr. Black—I want to say a few words about the Panas operation. At first I was impressed with the belief that we did not get a sinking of the caruncle. This led me to believe that it might be possible to accomplish a considerable effect upon a moderate amount of squint without actually doing a tenotomy, but simply following the Panas operation up to the point of stretching the muscle. I do not believe it would be of any value in cases of marked squint, but in cases of intermittent squint or small amounts of constant squint. Waiting for a favorable case to present itself, one of intermittent squint that had been under observation for a considerable interval came to me about six months ago. The child was about 12 years old and had been watched for four years. The hypermetropia was about 5 diopters and the case was almost well, but the parents were getting uneasy and I believed it best to perform an operation. Both interni were stretched and we had a marked divergence for about ten days with complete correction resulting in about thirty days without tenotomy. I have not had the opportunity to repeat this, but I have noticed in doing the Panas operation that if the hook is removed after the stretching we often have the divergence. It is possible that this would only be temporary in the majority of cases.

Dr. A. E. Prince, Springfield, Ill.—I have a word to say on the cosmetic aspect of the subject, in cases of paralysis of the rectus and extreme over-correction with limitation of motion. About fifteen years ago I operated several times with unsatisfactory results. Finally, I operated in a case of double overcorrection. A tramp doctor had stopped at a house and operated for internal squint in a boy for his lodging and $2.50. Later the eyes became extremely divergent and possessed almost no motion. I determined to make as bad an operation as my predecessor. Accordingly I made an exsection of half an inch of each external rectus so as to get behind the capsule of Tenon. An internal limiting suture was inserted which had the desired result and his eye remained cosmetically straight. Some years ago, at the invitation of Dr. Agnew, I operated at the Manhattan Eye and Ear Infirmary upon a case of paralytic convergence due to an injury. Patient's head had been jammed between two cars. In this case I exsected the internal rectus back to the apex of the orbit. The case was kept in the infirmary for some time as an exhibit case. Dr. Beard of

Chicago was the house surgeon at the time and remembers it. Since then I have exsected for paralytic strabismus a great many times with satisfactory results. Attention was called to this method of treatment in an article entitled "Section and Exsection of the Rectus," in THE JOURNAL of the Association, Oct. 13, 1888. I desire to mention it again, for every now and then I correct one of the cases which has been pronounced incurable by eminent oculists. I have had two cases who came to me requesting an enucleation rather than tolerate a motionless divergence; they would prefer a glass eye. In both cases the cosmetic success was eminently satisfactory.

DR. A. A. HUBBELL, Buffalo—I have had considerable experience in strabismus, and in the earlier part of my practice I approached it with a great deal of confidence from the operative standpoint. I got over that, however, a long time ago, and I now consider that it is one of the most unsatisfactory conditions we have to treat by operation. The first thing to be done is to endeavor to make clear in our minds the etiology of strabismus before we attempt any treatment whatever. Now, it must be admitted that concomitant strabismus, primarily, is a disturbance of innervation. It is a mistake, as I have said many times, to regard this affection as due to a weakness or over-strength of the muscles themselves. Taking alternating strabismus as an illustration, it can not be said that one internal rectus is too strong at one moment and the other at the next. The trouble is essentially with the centers of innervation which control the deviating movements. There may be a great deal of truth in Dr. Stevens' statement that a disturbance of innervation of the lateral muscles may be brought about by a hyperphoria, just as an error of refraction may produce the same effect. Perhaps the cyclophoria of Dr. Savage will do the same thing. We must thus take many things into consideration. The correction of errors of refraction is one of the primary steps to be taken toward relief, but it should be done early. Spectacles have little effect generally upon divergent strabismus, and if they are applied very early in convergent strabismus we may get a cure in a large percentage of cases, especially if the patient is old enough to practice the exercises mentioned by the other speakers.

I agree with some of the other gentlemen that it is a mistake to encourage the general practitioner to consider strabismus to be such a simple thing, and that it may be let alone until the child is 8 or 10 years old, when it can be easily and perfectly corrected by a tenotomy. We should see these cases early, as I have said, in order to get the best results from optical treatment; for later on they cease to be influenced by these measures, and operation, even with all its drawbacks and uncertainties, becomes necessary. The subject is a broad and difficult one, and I will close my remarks by confirming Dr. Ray's statement that alternating strabismus, in my experience, is a difficult condition to treat successfully by means of spectacles.

DR. C. A. VEASEY, Philadelphia—The method of correcting these cases which I have followed personally and which is also the method in use in the service of Dr. De Schweinitz at the Jefferson Hospital of Philadelphia, consists in a combination of some of the methods advocated here with modifications. In the first place, when a person presents himself with a condition of squint he is very carefully refracted and it is insisted that he shall wear a full correction constantly. If the case is a moderate one—and like Dr. Hotz we always make perimetric measurements of the angle before and after refraction—we at once begin to use the stereoscopic exercise, which is of benefit in moderate degrees, but of little use in high degrees. The patient is carefully watched, the angle of squint measured from time to time and if it is not making any improvement after a period of time, operation is advised. The operation performed depends upon the character of the squint. If alternating we usually find it necessary to divide it between the two eyes; if it is monolateral with amblyopia in one eye and of moderate degree of deviation we can usually correct it by an operation on the amblyopic eye. In the latter condition a complete tenotomy of one muscle is first performed, to be followed by advancement of the opponent if required. The operations are always done, except in young children, under cocain anesthesia, the angle being measured at different stages so that the effect may be controlled. Both eyes are bandaged or both are left unbandaged according to our control of the patient, the latter being preferable, and stereoscopic exercises are begun at once. In this way we are not only obtaining good results cosmetically but also in many cases binocular single vision.

DR. HIRAM WOODS, Baltimore—In reference to the contradictory reports as to the result in alternating squint I have been surprised that more stress has not been laid upon the acuity of vision in connection with the prognosis. My own experience has been that in cases of alternating squint with pretty nearly normal vision in both eyes the prognosis is good. I want to add a word of endorsement of Dr. Wilder's remarks with reference to the significance of abduction in testing these muscular conditions. This, with the parallax test of Duane, is the most important we have in determining the cause underlying the trouble. It is easy to see why faulty abduction is a valuable symptom, because the externus has an individual nerve supply. Abduction has not the same bearing. By Gould's exercise one can double or quadruple it in a few minutes. It is not so easy with abduction. Such a rapid increase apparently in muscular power seems to me nothing but the development of positive relative convergence, or teaching the patient how to separate C. for A.

DR. EDWARD JACKSON, in reply—Regarding alternating squint, there seems to be a confusion of different classes of cases. In cases of alternating squint with high ametropia and almost equal visual acuteness, I have found comparatively little difficulty. But there is a class of cases where the alternation clearly depends upon inability to turn the eyes in certain directions. With these cases there are great difficulties in treatment. The keeping of the eye open after operation is a very important point in the treatment of squint, and perhaps our greatest gain by a squint operation is in the breaking up of old habits of movement and leaving the eye for a time susceptible to the influence of non-operative treatment. The use of the eyes during these first few days after operation may be more important than anything else we can do in weeks of treatment afterwards. I might have said more about the stereoscope. I regard the ordinary form as about as valuable as the special ones that have been made for the treatment of strabismus. By varying the width of the pictures very different effects can be gained and there is an opportunity for inventive skill in furnishing the exercises for children. With regard to the strength or weakness of muscles, of course, that should be studied in every case before operation, and yet I have been decidedly disappointed in the effects of an advancement for convergent strabismus where I was sure the external rectus was the muscle at fault.

DR. C. F. CLARK, in reply—I should be very sorry to be put in a false position of being considered an authority upon strabismus. I regard our work in this line as merely a preliminary skirmish in the long struggle. I believe in the non-operative treatment, but we can not always use it, for there are hundreds of cases in which we must act quickly if we would do anything at all. Now, I think there is a decided limit to the value of non-operative treatment even where you might obtain the results. A well graduated and carefully worked out operation is often preferable to the hope long deferred and the effort to obtain that which you may not get in the end unless you have peculiar people to deal with. I am sorry that no one brought out exactly what they mean by an operation when they do operate; how far they confine themselves to the division of the tendon, or to what extent they divide the lateral fibers. I am coming more and more to the opinion that we should confine ourselves as far as possible to the tendon and leave the lateral fibers alone. In advancement, however, I think we should include the capsule with the tendon in order to get a good result.

A question was asked about the Fox operation. As soon as I heard Dr. Fox's paper I obtained his instrument and have been holding it in reserve until I could find a case in which

I would be willing to inflict the amount of traumatism he affects for the amount of correction desired. I do not like to operate in the dark as he seems to do. I feel deeply indebted to Dr. Prince for his forceps, which are to me invaluable, and by using them and the hook you can graduate your operations and have the whole of the tendon under control and determine how much to take off.

As to sutures, I generally prefer black silk because I can see them afterwards and remove them easily. As to the strength of muscles, I think we are using wrong terms in many of these cases. There are many cases where one muscle lacks strength or one is excessively strong, but I believe it is mostly a matter of innervation.

Dr. A. E. Davis, in reply—I wish to say that the test employed by me was in every case the perimeter whenever it was possible. There is one point in the Panas operation that I would like to emphasize, namely, that it can be employed in either divergent or convergent strabismus and without regard to the presence of hypermetropia or myopia. I think that if we fail to recognize the fact that strabismus is a binocular affection we shall fail to get good results; we must operate on both eyes in every case. I was glad to hear Dr. Prince's experience, for it accords with my own.

Dr. J. M. Ray, in reply—I formerly had very much the same idea in regard to the question of alternating squint as has been expressed here by Dr. Hotz and others; but when I began to study my cases, I found that the results did not accord with my opinion. On looking up the work of others, I find that the studies of Lang and Barrett, the monograph of Holthouse, and the recent work of Worth, all show as plain as figures can, that the correction of alternating squint, either by glasses or by tenotomy, is a more difficult problem to solve than is the correction of monolateral squint. My compilations show only 12 per cent. of cases of alternating squint cured by adaptation of glasses, while 30 per cent. of the monolateral ones were brought to parallelism by lenses. The same is true of the operation. Alternating cases are less often corrected by a single tenotomy, and advancements are more often necessary. As stated in the paper the externi are much weaker proportionately than in monolateral squint. My definition of alternating squint would include all squints that fix indiscriminately with either eye and where there is practically the same amount of vision in each.

TYPHOID FEVER—DIETETIC TREATMENT.

LOUIS FISCHER, M.D.
Visiting Physician to the Willard Parker and Reception Hospitals.
NEW YORK CITY.

The vital points to be considered in the course of treatment of typhoid fever are: 1. Exhaustion, from continued draining of the body, if a prolonged diarrhea exists; thus large quantities of serum are lost and the blood supply weakened. 2. Continued fever means continued loss of fat and muscle and rapid emaciation. 3. Loss of strength from recumbent position, and from absence of normal substantial foods. 4. Toxemia, showing its effect chiefly on the heart and circulating apparatus demands careful noting when stimulation is demanded. 5. Résumé of foods successfully used in a series of cases of typhoid. 6. The value of salines and especially the administration of saline infusion per rectum, and if coma prevails, its use by hypodermoclysis. 7. Albumin and salt administered subcutaneously. 8. Peptonization of foods; sterilization and pasteurization; use of raw milk in this condition. 9. The administration of water with and without carbonic acid gas. 10. If severe vomiting and gastric disturbance exists, feed per rectum and colon; if severe diarrhea and tenesmus prevails, feed per stomach.

Exhaustion.—When the body loses large amounts of serum, the volume of blood is diminished, and the skin appears parched and loses its normal elasticity; hence large quantities of water are indicated. This will be very grateful to the patient, especially during the febrile state. We must seek to supply this deficiency of liquid, abstracted from the body, by infusing large quantities of normal saline solution and giving frequents draughts of water to which the raw white of egg has been added. It is surprising to know how much albumin can be put into the body by gradually giving liquid draughts when the thirst demands it.

While it is a rare thing to find a nursling or an infant below one year of age having typhoid fever, even such children will digest small quantities of raw white of egg when fed at intervals of two and three hours. One of my favorite dietetic remedies is whey, which is made by peptonizing the milk at a temperature of about 115, beating up the curded milk with a fork until the curd is evenly divided, then straining this liquid whey through a cheese-cloth. When it is flavored by the addition of a few drops of lemon juice, or vanilla, or peppermint, we make it more palatable and do not disturb its nutritious properties.

Barley water, rice water, farina water, almond milk are all nutritious foods, easily digested and readily absorbed.

Toxemia.—If there is a distinct toxemia or evidences of profound systemic poisoning, nothing will be as useful as the introduction of large quantities of a normal saline solution, hypodermically. This can be injected into the abdomen by plunging a large aspirating needle into the deep cellular tissue to which is attached an ordinary fountain syringe holding about two quarts of water. Too much pressure is not needed for the introduction of a pint, or two pints of liquid; frequently, holding the syringe about two feet from the patient's body, will give ample pressure for its thorough introduction.

The lymphatics, during the febrile state, are usually so greedy that they will absorb several quarts of this normal saline solution and hence this important fact should be noted; the bowels and the heart's action should be carefully followed and a comparison made of the condition of the same, before, during and after the injection of this normal saline solution. It is advisable, if the patient has been benefited, to repeat these injections every six, twelve or twenty-four hours, depending on necessity. Flushing the system with this normal saline solution will carry off from the skin and kidneys large quantities of poison.

Rectal Feeding.—If the stomach rebels and vomiting is an urgent symptom, then we must try giving the stomach rest and rely on rectal feeding. For this purpose the rectum should be thoroughly flushed with normal saline solution, and one ounce of thoroughly peptonized milk, to which one ounce of starch water is added, should be injected in intervals of four hours.

Sub-cutaneous Feeding.—An important point to remember is, that the white of a raw egg can be added to the normal saline solution and injected hypodermically.

Thirst.—Carbonic acid water and water acidulated with dilute hydrochloric acid seem to be not only very well borne but appear to inhibit bacterial action, besides being very grateful to feverish patients.

The successful management of a typhoid fever case does not depend on the administration of drugs, excepting eliminatives, but depends solely on supporting the vitality of the child by giving it liquid foods, as above enumerated, and thus sustaining the heart.

REVERSIBILITY OF ENZYMES.

A most important addition to biological sciences is furnished recently by the observation that ferments, at least several kinds if not all, are capable of reversing their ordinary splitting action, and instead combine the separated substances into the substance they originally formed. For example, the renal epithelium, which has long been known to synthesize benzoic acid and glycocoll into hippuric acid when brought into contact with a mixture of the two substances, will act in an opposite manner when brought into contact similarly with hippuric acid alone, splitting it up into glycocoll and benzoic acid. In other words, enzyme action is like any other chemical reaction, in that the reaction is reversible.

This important property of enzymes was first demonstrated by A. C. Hill,[1] who approached the question in the way above mentioned, that is, with the object of ascertaining if enzyme action was reversible in the same way in which chemical reactions are. He was successful, for he found that maltase, a ferment which splits maltose into glucose, placed with a solution of glucose, will cause a certain number of molecules of glucose to combine to form maltose. Also, it was found that the end result was the same whether the enzyme acted upon maltose solution or upon glucose solution, for in either case the changes caused the production of a solution containing a mixture of maltose and glucose with the same relative proportions of each. It thus becomes evident that the enzyme brings about a certain equilibrium between the complete substance and its components. When that equilibrium is reached no further action occurs, but if we remove one of the substances, say by dialysis when this is possible, then the reaction will continue as long as equilibrium is not attained. Whether this reaction will be one of building or of splitting will depend upon which of the substances is in excess.

Lipase, the fat-splitting ferment, has been found also to act as a fat-forming ferment by J. H. Kastle and A. S. Loevenhart.[2] While this ferment is ordinarily thought of as a constituent of the pancreatic juice these authors and others have found that it is much more widespread, being present in the liver, submaxillary gland, and kidney of the hog, and also, which is of especial importance, in the epithelium of the small intestine. Indeed, the pancreas is not the chief place of its existence, for liver tissue has nearly three times as vigorous lipolytic action as the pancreas tissue. Hanriot has also demonstrated the presence of a powerful lipolytic enzyme in the blood serum, so it is to be presumed that the distribution of fat-splitting ferment is almost universal in the body, for if not present in the tissues of an organ it would be supplied by the blood flowing through those tissues.

Now, with this new knowledge both of the wide distribution of lipase and its double action, we are in a fair way at last to clear up the perplexing question of fat metabolism, both in health and disease. Take for example fat absorption from the intestine. It may now be considered to take place by some such steps as these: First the lipase of the pancreatic juice splits up fat into fatty acid and glycerin; by the laws of osmosis these substances would diffuse into the epithelial cells lining the intestine, but here, meeting the lipase of these cells, part would be synthesized into fat; and histologists have long since shown the presence of fat droplets in the absorbing epithelial cells. Next, in the portion of the cell nearest the lacteal stream the glycerin and fatty acid still uncombined would pass out by osmosis, and so the necessity of establishment of equilibrium would lead to a continuous splitting of the fat in this part of the cell, with liberation of more glycerin and acid. When these reach the blood stream equilibrium is re-established by the lipase of the serum. Probably the tissue cells utilize the fat in a quite similar manner.

Thus is explained by simple physical laws a process long puzzling to physiologists, who have often fallen back in despair to that fast-narrowing loophole of escape, the "vital properties of the cell." As new observations are rapidly pointing out the part played by enzymes in cell activities in ways hitherto unsuspected, the far-reaching importance of this fuller understanding of the manner of enzyme action is perceived.

PENNY-WISE DISINFECTION.

The full report of Governor Gage's special lay "health commission"—chiefly of newspaper men—has come to hand and is interesting and suggestive. Its conclusions and that of his "state board of health" that there is not and never had been any plague in San Francisco, and that the reports of its existence were based upon the diagnostic mistakes of such incompetent observers as Drs. Barker, Flexner and Novy, has already been noticed in The Journal. In this full report, however, there are other interesting details. After the agreement with the United States authorities as to disinfection and cleansing of Chinatown, the report says that the instructions of Dr. White, the government official designated to oversee the work, "were rigidly adhered to." This is important; but we read, a few lines farther on, the self-congratulations of the commissioners over their economy and that "by disregarding the recommendation of Dr. White to purchase sulphur, bichlorid of mercury, Dutch ovens, etc., in large quantities a considerable saving was

effected. Thus the work of disinfection and fumigation was thoroughly performed with 300 pounds of sulphur although the Marine-Hospital service estimated that 30 tons would be necessary. Fifty pans were bought and 20 only used, but the requisition of the federal official called for 200." These are valuable facts as showing the rigid adherence to instructions and the thoroughness of the work.

Some 30,000,000 cubic feet of dwelling apartments are said, by the board of health, to have been fumigated; thus one pound of sulphur was sufficient per 100,000 cubic feet, a fact in sanitation that is worth knowing. It is such admissions as these that make the report suggestive and enable one to estimate the general thoroughness of the work. We sincerely trust that the local San Francisco Board of Health, which has, we believe, manfully held its own way and opinion thus far as regards the plague cases in that city, will be able to ward off a serious outbreak of the disease, which, according to the Public Health Reports, still lingers in its Chinese quarters. If they fail they can not be much to blame when we consider the opposition of the state authorities and what it means. Should they fail and the pest really become epidemic the Governor and the creatures of his "boards of health" will probably find that they have been laying up for themselves a day of wrath.

One can not help comparing the methods adopted by the governing authorities in California with the methods adopted in foreign countries in bravely meeting this foe and not denying its existence, especially the open recognition of its existence by the authorities in Glasgow and the energetic methods adopted to suppress it. The disgraceful way in which the Governor of the great state of California and his creatures have acted in regard to this epidemic is a reflection not only on the city of San Francisco and the state of California, but on the United States.

RAILWAY SANITATION.

According to a Berlin dispatch. the Prussian state railway authorities are taking special precautions against the spread of contagion by public conveyances under their charge. They even propose to go so far as to have a physician accompany through trains and the station masters are to furnish him with detailed reports of typhoid cases, etc., occurring in their towns or any suspicions of such. Sterilized water tanks are to be put up and conspicuously labeled and fresh boiled water supplied. All precautions against infection are to be employed about the stations, which will be practically quarantine stations. All this is said to be on account of the spread of typhoid, but it is to be presumed other infections will not be disregarded. Any person who travels and who has even an ordinary eye to sanitary defects can see many opportunities for mischief in railway carriages, and it is said that aside from the spitting nuisance, matters are worse in European travel than in this country. One probable good effect of the public scare as to tuberculosis, etc., which has not yet reached its climax, will be to improve matters, and it is even possible that the expectorating nuisance may be put down. The important point is that the right thing be done; it is too much to expect that only this will be attended to; there will undoubtedly be many mistakes. If we can feel that decent disinfection, comparative cleanliness and just, reasonable and practicable precautions against infectious disease are the rule, and spitting is suppressed, we can trust to our vital resistance for the rest and travel with comparative comfort. The Western Passenger Association, it is reported, is to consider a demand from the Travelers' Protective Association that traveling consumptives be isolated. It might be well if this could be done, but there are enough infected individuals whom hardly anything short of a tuberculin test could reveal, to make such an attempt ineffective. Every passenger would have to be examined to insure full protection, and this is a manifest impossibility. In the meantime we need not forego altogether the pleasure of travel on account of the perils that have always existed, even to a greater extent than at present, and of which we are only now becoming fully aware.

Apropos to the above it may be added that the Russian bureau of railways has also published rules in regard to travelers, requiring all cases of infectious disease on railroad trains to be at once removed and put in charge of the police at the nearest station where medical care can be given. Any car in which a case of smallpox, scarlet fever, diphtheria, typhoid or dysentery has occurred must be detached and disinfected. In case of other infectious disorders the question of disinfection, etc., is left to the judgment of the medical official.

MORE SANITARY SLEEPING-CAR ACCOMMODATIONS NEEDED.

In another column a correspondent calls attention to a nuisance that, it is rather strange, has not received more attention heretofore, viz., the promiscuous and varied use of the washing apparatus on sleeping-cars. Any one who has utilized these extensively can corroborate our correspondent's charges. Personal cleanliness is praiseworthy, and tooth-brushing an essentially sanitary measure, but, like some other salutary performances, it should be done with some regard for public decency. Hawking and spitting into a public wash-bowl and blowing one's nose into it are offenses that come pretty near to, if they do not quite reach, the climax of offensiveness. It is possible, perhaps, to imagine worse ones, but there is no need of it. For years the writer has followed; in public wash-rooms, the custom of washing only from the spout, and there are many others who do likewise, but this can not be done in the contrivances of the railroad car. There is no reason why railroad and sleeping-car companies should not follow our correspondent's suggestion and add separate tooth-washing sinks and enforce their usage. We have yet a few wrinkles of civilization to adopt, and this is one.

ANOTHER FAITH DELUSION.

A "christian science" writer evidently wants to climb with his fad into the band-wagon. Noticing the improvement in mortality statistics during the past decade he immediately correlates it with the growth of his delusion. He says: "While investigators may ascribe this remarkable improvement to different causes, according to their point of view, these figures prove conclusively that at the same time that 'christian science' has been sweeping over the country from end to end, health and longevity have made great conquests over sickness and death." It is a common observation in psychiatry that the morbid mind applies everything to itself and its own agency, and this utterance has much of that appearance. It was taken, however, from a communication to an insurance publication and there was probably an idea that it might pass for an argument or evidence in favor of Eddyism with insurance officials, who have not shown a tendency to favor that cult in a business way. We might as well credit the reduced mortality of the last ten years to the influenza as to Eddyism; the same reasoning will apply to both, but the Eddyites won't see it.

THE INFLUENCE OF CONCENTRATION AND OF THE NUMBER OF SITES FOR HYPODERMIC INJECTION.

There is a belief in some quarters that drugs taken in undiluted form are more active than when taken diluted, but this view is not generally accepted. It would on the same line of reasoning be expected that medicaments administered hypodermically would be the more active the more concentrated their form. Of this, some observations recorded by Dr. S. J. Meltzer[1] would seem to supply evidence, as well as of the further fact that the intensity of action can be increased by making the injection in more than one situation. The observations were made in the course of experiments disproving an assertion that had been made to the effect that animal tissues are capable of neutralizing or fixing the poisons of strychnin and venom. When the minimum effective dose of strychnin divided into three equal parts was injected into three of the previously ligated extremities of a guinea-pig violent convulsions occurred as soon as the ligatures were removed. These convulsions were more pronounced and set in earlier than those induced by injection of the whole amount into a non-ligated member. Further experiments showed that injection of a given quantity into three unligated members was followed by more profound effects than injection of the same amount into a single unligated member. Finally, it was found that the injection of a given amount of strychnin was followed by far less pronounced effects when the dilution was greater, and even if larger amounts of the drug were used. These observations accordingly demonstrate that the effects of subcutaneous injections depend upon the concentration of the solutions injected and are materially influenced by a greater distribution of the injected quantity over several areas.

VIVISECTION IN POLITICS IN MASSACHUSETTS.

There is a little paper called the *Animal Defender* devoted to general misrepresentation, in behalf of the causes of anti-vivisection, anti-vaccination, etc. In its latest issue it reproduces the letter of President Brown of the American Humane Association, published in The Journal October 19, and says in comment thereupon: "Some of the worst instances of human vivisection have been openly confessed by their perpetrators in The Journal's columns within the last two years; and no word of criticism or reproof has ever accompanied them." Our readers can appreciate this misrepresentation—we might use a stronger and more emphatic term—without our dilating upon it; it is mentioned to show what sort of reckless statements are emitted by these zoöphile fanatics. We call them fanatics in charity, though a much worse designation might better fit. Their literature is circulated among the people and undoubtedly creates a certain amount of public sentiment, and may even influence legislation. In the same issue is published the status of Massachusetts' legislative and state candidates at the coming election regarding the question of legal restriction of vivisection, as given by answers to a circular letter sent out by the New England Anti-vivisection Society. A plea is made for all supporters of the cause of zoöphily to note these replies and select their candidates accordingly. As they are introducing the subject into politics it would be well hereafter for the medical profession to see that legislators are duly enlightened. The matter is called to the attention of the profession in Massachusetts especially. Those who estimate the prohibition of the alleged sufferings of a few animals utilized for the benefit of our race as "the most important matter before the world to-day," therefore above even the temporal and spiritual salvation of mankind, are not very safe advisers.

THE MICROBIC FLORA OF THE MOUTH OF NURSLINGS.

The importance of microbes both in health and in disease fully justifies all studies that tend to throw light upon their relations to the human body. The microbic flora of the mouth has been studied extensively in the adult, but in the case of the newborn and in the nursling, in which the conditions are in every way simpler and less complicated, a beginning only has just been made in the study of the buccal bacteria. Lewkowicz[1] carefully examined the mouths of several nurslings according to improved methods, and his results indicate that streptococci are the earliest and most numerous bacteria to appear. A pneumococcus of little or no virulence is also quite constant. Other micrococci were also found, but in no case did he meet with any pyogenic staphylococci. Among the bacilli an acidophile form is most frequent. Later on, strict anaërobes are found. Their existence in a cavity so well aërated as the oral is probably due to the presence of numerous recesses into which the air penetrates with difficulty, and also to the action of the numerous aërobic forms which use up all the free oxygen and thus establish the conditions necessary for anaërobism. One of these anaërobic organisms, bacillus bifidus communis, forms a large part of the intestinal flora in nurslings and it seems to make its appearance in the mouth and in the intestine at about the same time. The author also succeeded for the first time in cultivat-

1. Arch. de Med. Exp. et d'Anat. Path., 1901, xiii, 633-660.

ing the leptothrix buccalis, which is also a strict anaërobe. Studies of this sort must form the basis for an appreciation of the importance of variations in the bacterial species in pathological states, whether general or local. Then the much richer and more variegated buccal flora later in life is studied with better understanding if we go upward from the simpler conditions in the newly born to the adult in whom the anatomical relations are more complicated and the food-supply a great deal more varied.

LOMBROSO ON ROYAL CRANIA.

According to the Paris dispatches, the savants of that capital have not the reverence for potentates and fear of *lèse majesté* laws in their mental make-up to any great extent. They recently enjoyed a lecture from the celebrated Italian anthropologist, Professor Lombroso, who was feted by them on his way home from the Amsterdam Congress of Criminology, in which he discussed the characteristics of contemporaneous rulers, using as illustrations a series of casts of their craniums furnished by Virchow. Most of them were found by him to be criminals or lunatics, the exceptions being the Czar of Russia, who is a sort of harmless innocent, and King Edward VII, who is only somewhat more than the ordinary average of mediocrity. The Emperor of Germany he considers a born tough, who under ordinary conditions would probably come to the gallows, and the Sultan of Turkey would in common life be a sneak thief. Details are wanting as to Professor Lombroso's opinion of the other royal personages, but others have endorsed his views that Europe is in the hands of idiots, rascals and lunatics. It had seemed to us before that modern royalty was, in spite of its many faults, rather a good lot as compared with their predecessors, and that while the institution of royalty was unfortunate in giving responsible position to those handicapped by a bad family history, it was at present better represented than might have been expected under the circumstances. We are not surprised at the verdict on the Sultan, but as for the rest it seems still a little harsh. In fact, such a wholesale disparagement of exalted personages has almost an anarchistic twang, and we doubt whether it is profitable even if there is a basis for it. Emperor William would probably make it unprofitable if he could, and Professor Lombroso need not be surprised if he should some time find himself *persona non grata* on venturing within his jurisdiction. Possibly, Lombroso himself, if he could see himself in a purely objective way, might find considerable abnormality and degeneracy in his own cranial and mental organization.

SYPHILITIC ENTERITIS SIMULATING MELENA IN THE NEWBORN.

Hemorrhage from the bowel is naturally only a symptomatic manifestation in children as well as in adults. Intestinal ulceration and erosion of a blood vessel constitute the most obvious cause, although the bleeding may take place in connection with a condition of hemophilia. A case has recently been placed on record by Dr. Jos. Esser,[1] in which enteritis of syphilitic origin in a newborn child was attended with fatal hemorrhage from the bowel and which is of especial interest on account of the underlying disorder. An illegitimate female child, with jaundice, began on the fifth day of life to have bloody stools, which continued until death occurred on the tenth day. On the sixth day a rapidly progressive bluish-red swelling appeared on the dorsum of the left hand and ruptured toward night, discharging blood. On postmortem examination there was found, in addition to osteochondritis, indurated enlargement of the spleen and vascular changes, and thickening of the jejunum with ulceration of the mucous membrane. Also the follicles of the ileum and the colon and the mesenteric glands generally were enlarged. Microscopic examination disclosed cellular infiltration of all of the coats of the intestine, particularly about the smaller vessels, causing occlusion and necrosis with ulceration. The walls of the splenic vessels, especially the smaller and the medium sized, were thickened, particularly the adventitia and the media, and the lumen was narrowed. Hyperplasia of the stroma adjacent to the larger vessels was present and the pulp cells contained a considerable amount of black granular pigment. The spleen contained also small areas of necrobiosis. The subcutaneous connective tissue related to the lesions on the hand was infiltrated with blood and the middle coat of the vessels—both arteries and veins—was greatly thickened. The vasa vasorum were in some instances surrounded by cellular infiltration, and in some places the elastic fibers of the intima were torn and the wall and the surrounding tissues suffused with blood.

1. Archiv für Kinderheilkunde, 32 B., 3 u. 4 H., p. 177.

TETANUS FROM ANTI-DIPHTHERIA SERUM.

A considerable number of children in St. Louis have been infected with tetanus by the injection of anti-diphtheria serum. A number of deaths has occurred from tetanus in children treated with diphtheria antitoxin either for curative or prophylactic purposes. This antitoxin was manufactured by the city of St. Louis, and the statement is made that the horse which furnished the serum developed tetanus. It is also stated that a guinea-pig injected with the diphtheria antitoxin used in these cases promptly developed tetanus. Whatever truth there may be in these startling statements they certainly are calculated to strike a note of alarm and of regret that there should have happened anything that even remotely corresponds to the news reports. There is to be considered not only the sad fate of the children who possibly escaped diphtheria only to die of tetanus, but also the general effect which such lamentable mishaps are sure to exercise upon the public. The medical profession knows only too well to what evil purposes happenings of this kind are used by the anti-vaccinationists, anti-vivisectionists, "christian scientists," and crotchety persons in general. Prejudice and fear thus engendered among the communities may cause a degree of harm that in the end becomes immeasurably greater than the immediate damage. One of the most important and also difficult rules for physicians, since the days of Hippocrates, "first of all do no damage"—πρῶτον τὸ μὴ βλάπτειν—is called to mind by the immediate and remote consequences of occurrences like the one reported from St. Louis. The unavoidable and unforeseen difficulties in the way of always carrying out this precept, the wisdom of which no one

denies, are a matter of familiar experience to practitioners of medicine. It is not always possible to control fully the circumstances surrounding the production and handling of many of the powerful and complicated agencies used with general success in combating dangerous diseases. This is not the first time that fatal tetanus has resulted from the injection of diphtheria antitoxin, and in all probability it will not be the last time; thus there is placed upon those that undertake its manufacture a tremendous responsibility which should and no doubt does stimulate to ever renewed and redoubled vigilance. Physicians everywhere should ever bear in mind that even a puncture by a hypodermic needle may be the means of introducing the most dangerous infections, the agents of which may occur in the fluid injected, upon the instrument used, and upon the skin of the patient.

Medical News.

COLORADO.

St. Luke's Hospital, Denver, is to have a $60,000 addition to accommodate 40 patients. During the last fiscal year 1027 patients were received at the hospital and 602 operations performed. Among the directors, all of whom were re-elected, were Drs. Frederick J. Bancroft and Edmund J. A. Rogers.

New Health Orders.—The Board of Health of Colorado Springs, desiring to avoid a repetition of last winter's epidemics, has issued orders for the connection of all houses with sewers, or when this is impossible, the combination of vaults and cesspools in accordance with the requirements of the health ordinances. A second order holds those in charge of private or parochial schools responsible for the strict enforcement of the compulsory vaccination law and the observance of the ordinances regarding infectious, contagious or communicable diseases.

DELAWARE.

Smallpox is reported in Bethel with three cases, one patient being in a critical condition.

Dr. Columbus Henry, Newark, has been appointed trustee of the poor farm, White Clay Creek Hundred.

Dr. Swithin Chandler and wife of Wilmington, are spending a year in Europe where Dr. Chandler will take up special studies in Vienna, Berlin and Paris.

DISTRICT OF COLUMBIA.

Army Changes.—Lieutenant-Colonel Ezra Woodruff, deputy surgeon-general, U. S. Army, was placed on the retired list, October 24.——Dr. Charles H. Andrews, acting assistant surgeon, U. S. Army, was appointed major and surgeon of Volunteers, November 2.

Government Hospital for the Insane.—Ground has at last been broken for the addition to the hospital, for which $1,000,000 was appropriated. The extension is to accommodate 1000 patients and 200 employes. The trustees recommend an additional appropriation of $145,000 for an administration building, of $150,000 for a central heating and power plant, and of $20,000 for an enlargement of the kitchen, and of $495,000 for the care of 2250 inmates at an estimated cost of $220 per capita.

Freedmen's Hospital.—In his annual report, Dr. William A. Warfield, surgeon-in-chief of the Freedmen's Hospital, Washington, recommends the erection of a new building large enough to gather all the various wards of the hospital under a single roof and equipped with the needed appliances of a modern hospital. The present buildings are all old frame structures, difficult to heat, troublesome to ventilate and inaccessible. During the fiscal year 2552 patients were cared for in the hospital and 5084 persons received treatment in the out-patient department.

Waldeyer's Washington Welcome.—Dr. Heinrich Wilhelm Gottfried von Waldeyer, president of the Berlin Academy of Sciences, visited Washington, October 30. He was entertained by Dr. Charles Wardell Stiles at his residence, welcomed in characteristic way by the students of the Georgetown Medical College, whom he addressed in German, his remarks being translated by Dr. George M. Kober, dean of the college; received by the president; tendered a luncheon at the Jesuit College, a reception at the Department of Agriculture, a dinner by Dr. Stiles and a reception by the Cosmos Club.

ILLINOIS.

Bond County Medical Society has decided on a fee-bill allowing $1.50 for day calls and $2.00 for night calls in town.

Unknown Donor.—A gift of $15,000 to Northwestern University, Evanston, is announced. The donor is a wealthy physician of Ohio who desires to do good by stealth.

Brokaw Hospital.—The new building for this hospital, built at a cost of $20,000, will be ready to receive patients by the middle of November. The building will accommodate 55 patients.

Alice Home, the public hospital at Lake Forest, erected and donated to the village by the Durand family, is to be enlarged by the erection of a contagious disease ward to cost $8,000, donated by Mrs. H. C. Durand.

Smallpox.—Red Bud has 27 cases of smallpox, with one death; Hamilton, 16 cases; Wythe Township, several cases, and Mount Auburn, 3 cases. Quarantine has been established and all schools at Hamilton and Elvaston have been closed.

Personal.—Dr. John Haig, Leroy, has been compelled to retire temporarily from practice on account of his eyes.——Dr. E. R. Motley, Kinderhook, has sold his practice to Dr. Charles W. Trautwein, and will move to Virden.——Dr. Charles E. Wilkinson, formerly of Monticello, has returned after 18 months spent in study in Europe, and has located in Danville.

Chicago.

Dr. George W. Hall has been appointed neurologist to Cook County Hospital.

Scientific research under the auspices of the Rockefeller fund will soon begin under the direction of Dr. Ludvig Hektoen. Dr. J. C. Friedman will devote his whole time to original investigation.

Personal.—Dr. Arthur R. Reynolds, Health Commissioner, visited the Buffalo Exposition last week.——Dr. Alfred Hakanson has returned from Europe and has opened an office at 100 State St.

A New Journal.—The Chicago Pathological Society will hereafter publish its transactions in journal form in place of the annual transactions. Number 1, vol. v, of the new series has just been received.

"Passing-Up". Tabooed.—Two students of the University of Chicago have been suspended for participating in "passing-up" fellow students, a custom which the authorities of the university have prohibited.

Health Department Guiltless.—Judge Tuley on October 31 directed the jury to bring in a verdict of not guilty in the case against Dr. Arthur R. Reynolds, Commissioner of Health, and Mathias Brand, formerly a member of the Board of Health, in the suit of Mrs. Mary E. Moore, who sought to recover $25,000 damages on account of alleged detention in the isolation hospital.

The Week's Mortality.—During the week ended November 2 there were 408 deaths reported to the Health Department, this being 34 fewer than the preceding week, but 22 in excess of the corresponding week of last year. The week's mortality record was the second lowest during the year, the death rate being but 12.08 per thousand of population. Fewer deaths than customary from acute intestinal diseases; diphtheria, heart diseases and nervous diseases chiefly contribute towards the low mortality rate. There were 23 deaths from typhoid fever during the week, or 7 fewer than the preceding week, which was the highest point reached in several years.

INDIANA.

Smallpox is reported epidemic at Glendale, Daviess County, where 27 cases have occurred, and at Union City.

Linton Physicians' Club.—The physicians of Linton have organized a club for social and scientific purposes, which meets every Wednesday evening.

"Dr." Earl C. Smith, Indianapolis, set down in Polk as an eclectic physician, has been held under $300 bonds at Madison for practicing without a license.

Diphtheria is prevalent at Shelbyville, where one school has been closed, and in the southern part of Scott County. The spread of the disease at Knox and North Judson has been checked.

Board of Health.—The Mayor of Indianapolis has named as the new City Board of Health, Dr. George H. E. House, president; Dr. George H. F. Kahlo, Dr. Frederick C. Heath, and Dr. Eugene Buehler as city sanitarian and secretary to the board. The new board has appointed Dr. Norman E. Jobes, superintendent of the City Hospital, and Dr. Charles O. Lowry, superintendent of the City Dispensary.

Personal.—Dr. B. D. Brown, Indianapolis, has been appointed assistant superintendent of the East Tennessee Hospital for the Insane at Lyon's View, Knoxville, vice Dr. Clio Collier, resigned.——Dr. I. J. Vaughan has returned to Topeka. ——Dr. Alva L. Spinning has located in Michigan City.——Dr. H. B. Shacklett, Leavenworth, has moved to New Albany.—— Dr. Joseph E. Ziliak, Haubstadt, has moved to Linton and formed a partnership with Dr. Sam N. Quillian.——Dr. W. E. Kessinger has moved from Scotland to Sandborn.

IOWA.

The Southeastern Iowa Medical Society will meet at Burlington, November 26.

The Constitutionality of the state law regarding osteopaths is on trial. The suit of Parsons against the State Board of Medical Examiners was begun before Judge Holmes, at Des Moines, October 31.

Personal.—Dr. Mary C. Heilesen has located at Shenandoah.——Dr. Albert M. Barrett, Independence, sailed for Europe, October 22, where he expects to study for six months and then return to become one of the staff of the Danvers (Mass.) Insane Hospital.——Dr. Ernest E. White, Pleasant Plain, has moved to Knoxville where he is associated with Dr. Norman R. Cornell.

LOUISIANA.

New Orleans' Mortality.—The mortality of New Orleans for September among whites was at the rate of 12.52 per 1000 per year. The mortality among the colored population is not given.

Physicians Licensed.—The State Board of Medical Examiners, at its meeting October 24 announced that 17 out of the 31 candidates examined had passed. Three candidates were colored, of whom one passed.

Yellow Fever Institute.—The following New Orleans physicians have been selected as civilian members of the Yellow Fever Institute, created by Act of Congress in March last and placed in charge of the United States Marine-Hospital Service: Drs. Felix Formento, Henry A. Veazie and Lucien F. Salomon, and Professor Beyer of Tulane University. The Institute will be divided into four sections, the first of which will concern itself with the history and statistics of the disease, including the relation of the slave trade and modern sanitation. Section B will be occupied with the cause of the disease, while Section C will specially study its transmission by the mosquito. This insect will be studied from all points. Its life and habits will be thoroughly investigated, and the question whether its progeny may be infected through the parent insect, and whether infection may be conveyed by other than its means worked out. Section D will consider quarantine and treatment. The main lines of study of this section will be whether disinfection of baggage is necessary to prevent the spread of the disease; the treatment of the patient, the immunity of individuals and of races, individual prophylaxis and communal prophylaxis by means of sanitation.

Charity Hospital Appointments.—At the recent meeting of the Board of Administrators of Charity Hospital, New Orleans, the medical committee submitted the following-named visiting staff for the half-year: Visiting physicians—Drs. P. Emile Archinard, Thomas S. Kennedy, Edouard M. Dupagnier, Lionel A. Cazenavette, Abraham Nelken, J. Moore Soniat, Joseph M. Elliot, Arthur Weber, Narcisse F. Thiberge, George S. Bel, L. C. Chamberlain, Henry B. Orr, John B. Elliott, Louis F. Reynaud, Jacob A. Storck, Otto Lorch, Edward J. Huhner, W. B. Robertson, Louis G. Le Beuf, William H. Seeman, J. A. Danna, William W. Butterworth, Jacob Barnett, Henry Bayon, G. King Logan and John B. Elliott, Jr.; visiting surgeons—Drs. Ernest S. Lewis, Paul Gelpi, C. Jefferson Miller, L. B. Guthrie, L. Thibaut, Charles L. Chassaignac, E. Denegre Martin, Henry S. Cocram, W. M. Perkins, Marion Souchon, Luther Sexton, Sidney P. Delaup, S. M. D. Clark, Hermann B. Gessner, Charles A. Borey, Rudolph Matas, Albert S. Yenni, Edmond Souchon, Eugene H. Walet, Edmund Moss, J. Lewis, C. Perrilliat, Frederick W. Parham, Paul Michinard, Felix A. Larue, John F. Oechsner, Clarence L. Horton, S. W. Stafford, Marion H. McGuire, William E. Parker, I. I. Lemann, Hampden S. Lewis, Jules Lazard and C. N. Chavigny; visiting aurists, rhinologists and laryngologists—Drs. J. Phares O'Kelley, Otto Joachim and Edward W. Jones; visiting oculists —Drs. Edward W. Jones, Otto Joachim and Paul L. Reiss; dermatologists—Drs. Isadore Dyer and Ralph Hopkins.

MARYLAND.

Baltimore.

The semi-annual meeting of the Medical and Chirurgical Faculty will be held at Elkton, Cecil County, about the middle of the month.

Mortality and Morbidity.—The city has been free of smallpox since early in July. The deaths for the week ended November 2 were 178; only 2 died from typhoid fever and 12 from pneumonia.

Editions of Hippocrates.—Dr. Howard A. Kelly has 150 editions of the works of Hippocrates. This is, without doubt, the finest and most complete collection of the writings of the "Father of Medicine" in America, if not in the world.

Dr. John C. Hemmeter's book on "Diseases of the Stomach" has been translated into German, and a French edition is also in preparation. The whole of the fourth edition—5000 copies—of Osler's "Practice" has been sold and a reprint will be necessary.

Personal.—Dr. Albert Scott Harden sailed on October 28 to complete his medical studies in Europe.——Dr. John Montgomery West will sail shortly to spend several years at German universities.——Dr. Sidney O. Heiskell has resigned as chief surgeon of the Maryland Naval Reserves; Dr. Alan W. Smith has been appointed to fill the vacancy.

Repeal of Infectious Diseases Hospital Ordinance.—The action of the city council in repealing the ordinance creating the Infectious Diseases Hospital Commission and re-enacting the same is a temporary death-blow to our hopes of securing this long-needed institution; it deprives the commission of the appropriation and other resources for building and paying for the site already chosen. The property was in all respects suitable and the only drawback was the objection by neighbors to the location there.

New Section Organization.—The new place for the organization of sections by the Medical and Chirurgical Faculty was put into effect on November 1, when the Section in Clinical Medicine and Surgery was organized by the election of Dr. L. McLane Tiffany as chairman, and Dr. John Ruhräh as secretary. Dr. Osler exhibited a case of scurvy and Dr. Ruhräh gave a lantern demonstration of syringomyelia and other affections. About 75 were present. There are five sections at present contemplated; they will meet in turn on Fridays.

MICHIGAN.

Scarlet fever has broken out in Montgomery and the public schools have been closed.

Dr. Donald Maclean and Dr. Max Ballin, Detroit, have located in the Grand Circus Building, 271 Woodward avenue, and announce that their practice will be limited to consulting and operative surgery.

Personal.—Dr. Della P. Pierce, Kalamazoo, is convalescing from typhoid fever.——Dr. Grant Ide, Dutton, has disposed of his practice and is visiting in Oshtemo and Mattawan.—— Dr. Frank A. Waples, Battle Creek, has left that city for New York.——Dr. William H. Matchette, Dollar Bay, has located in Hancock.

MINNESOTA.

Dr. Homer P. Dredge, Belview, has been elected coroner of Redwood County, vice Dr. Arthur B. Hawes, Redwood Falls, resigned.

Personal.—Dr. Samuel H. Boyer, Duluth, was seriously injured in a runaway accident, October 24.——Dr. David F. Rae, Pelican Rapids, has moved to Fergus Falls.

Smallpox is reported as follows: Red Lake Falls has 30 cases and schools and public buildings are closed; St. Paul has 3 cases; a patient with well-developed smallpox drove into Red Wing from Bay City, Wis.

Vaccination Requested.—At the Grant School, Minneapolis, two children were exposed to smallpox, and the board of education has requested that all unvaccinated children be

vaccinated in accordance with the direction of the Board of Health.

Physicians in Partnership.—Drs. James B. McGaughey, Edward D. Keyes, Nathaniel S. Lane, Donald B. Pritchard, Hans M. Lichtenstein, Oswald Leicht and Hugh F. McGaughey, Winona, have formed a partnership which became operative November 1.

MISSOURI.

A medical department is to be added to St. Louis University provided the necessary funds for its establishment can be raised. It is said that substantial promises have already been made.

Tetanus from Antitoxin.—Thirteen deaths from tetanus following injection of diphtheria antitoxin are reported from St. Louis. It is claimed that the use of impure antitoxin is responsible for these fatalities, but the facts will be undoubtedly brought out at the inquiry which is to be held. The antitoxin in question was prepared under the supervision of the city bacteriologist.

Personal.—Dr. Louis P. Butler, Casco, who has recently returned from Europe, is about to locate in St. Louis.——Dr. Jerome K. Bauduy, St. Louis, broke his left arm and sustained other serious injuries in a fall, October 20.——Dr. Edgar S. Harris, Tarsney, is taking a post-graduate course.——Dr. William T. Edwards, Avilla, has moved to West Plains, where he will take over the practice of Dr. Henry C. Shuttee, who has located in El Reno, Okla.

Smallpox is epidemic in Independence. It is said that there are more than 100 cases there, that the houses where smallpox exists are not placarded and that there is no attempt at quarantine. The State Board of Health is considering the advisability of establishing quarantine in order to protect the surrounding territory and especially Kansas City. The warden of the State Penitentiary has notified the sheriffs throughout the state that on and after November 15 no prisoners will be received at the penitentiary unless they shall have been vaccinated at such time as to make it safe to admit them.

NEBRASKA.

Scarlet fever at Hyannis caused the public schools to be closed, October 28.

Typhoid fever is epidemic in Harrison township, Knox County, where there are now 35 cases.

Hospital to be Fireproof.—The State Board of Public Lands and Buildings has decided that the reconstructed Norfolk Hospital for the Insane shall be fireproof.

To control smallpox the State Board of Health has demanded that every physician in the state report to the Board by letter every case of smallpox coming under his notice, within 24 hours thereafter under pain of revocation of his certificate to practice.

Smallpox is epidemic on the Winnebago reservation, where 53 are already said to have died from the disease. It is said that 200 cases now exist and that the Indians have no adequate medical attention. The surrounding country maintains quarantine against the reservation.

Personal.—Dr. James A. Andrews, Eustis, who was injured by a kick from a horse three weeks ago, is slowly recovering at a sanatorium at Lincoln.——Dr. Fred E. McKeeby, Red Cloud, has decided to locate in Colorado, where his father is already in practice.——Dr. W. J. Ryan, Omaha, has located in Union.

NEW HAMPSHIRE.

Dr. Albert E. Brownrigg, for three years assistant physician at the New Hampshire State Hospital for the Insane, has accepted an appointment as resident physician at the Highland Spring Sanatorium, Nashua.

Personal.—Dr. John W. Staples, Franklin, has moved to Worcester, Mass.——Dr. James A. Day, Claremont, has located in Waltham, Mass.——Dr. George W. McGregor, Littleton, will spend the winter at Pinehurst, N. C., as house physician at the Carolina.——Dr. M. W. Work, Marlow, has located in Keene.——Dr. John L. Walsh, Concord, has opened an office in Proctor, Vt.——Dr. Francis W. Lamb, Tilton, has gone to New York, where he intends to devote several months to post-graduate study.

NEW YORK.

Scarlet fever has broken out in West Utica. In the last few days 14 cases have been reported.

Personal.—Dr. C. B. Albright, Williamson, has located in Keene, N. H.——Dr. William E. Curtin, Amsterdam, has opened an office in Cohoes.

New Oswego Hospital.—The plans for the addition to the Oswego City Hospital have been approved. The building will be 58 by 38 feet and will cost $25,000.

Diphtheria is epidemic at Greenfield, a small village near Findley's Lake. Several persons have died owing to a failure to use antitoxin promptly. Antitoxin is now being used freely, and it is hoped that no more deaths will occur.

Buffalo.

Dr. Ferdinand Henrotin, of Chicago, addressed the Obstetrical Section of the Buffalo Academy of Medicine concerning the diagnosis and treatment of the various forms of septic pelvic diseases.

Ptomain Poisoning.—Several cases of ptomain poisoning have been reported in this city, and in every case the source of the milk was derived from one milkman. The Health Department is investigating the cause of the trouble.

Smallpox Well Guarded.—There are two cases of smallpox at the Quarantine Hospital, both of which are doing well. Buffalo, with its many foreigners who congregated here during the Exposition, may well consider herself fortunate in the small number of cases reported, but we are by no means assured that all danger is over now that the Exposition is closed. The city would have been in a pitiable plight had an epidemic occurred, because through the selfish motives of the aldermen, Health Commissioner Wende's urgent appeal for a modern quarantine hospital was not acted on, and the present quarantine hospital is an excellent example of what a hospital should not be, and does not deserve to be termed a hospital. It is to be hoped that a modern quarantine hospital for the care and study of infectious and contagious diseases will be established by the municipality of Buffalo. Great credit is due Dr. Wende for guarding the city from smallpox. There were times when the city was spared from the ravages of this epidemic by his alertness.

New York City.

German Hospital, Brooklyn, has received an anonymous gift of $5000.

Dr. Edward Wallace Lee, formerly of Omaha, and for the last year in St. Louis, has located permanently in New York City.

Prospect Heights Hospital and Brooklyn Maternity.—Under this title the Brooklyn Maternity and New York State School for Training Nurses will henceforth be known. Failure to secure an appropriation from the city has necessitated this change.

New York Skin and Cancer Hospital.—Dr. L. Duncan Bulkley will deliver a series of clinical lectures on "Diseases of the Skin," in the out-patient hall of the hospital, on Wednesday afternoons, commencing November 6, at 4:15 p. m. The course will be free to the medical profession.

American Association.—We have received circulars, etc., sent out by a concern in New York City which calls itself the "American Association." It is evidently a kind of collection agency, especially soliciting membership from physicians. A correspondent suggests that we call attention to the fact that it has no connection whatever with the AMERICAN MEDICAL ASSOCIATION.

OHIO.

Smallpox.—Only six cases of smallpox remain at Newark. ——Findlay is threatened by a smallpox epidemic.

Personal.—Dr. Frank B. Humbert, Mount Liberty, has moved to Orrville.——Dr. Francis N. Pilcher, Guysville, has located in Columbus.——Dr. J. Milton Long, Zanesville, has moved to Massillon.——Dr. Steele, Frost, has located in Guysville.

Asylum Overcrowded.—On account of the overcrowded condition of the State Hospital for the Insane at Newark, the trustees of that institution have recommended an appropriation for the establishment of several new wards, including a special building for acute cases.

Physician Wins Suit.—Dr. Joseph D. Ely, Toledo, whose bill was contested on the allegation of malpractice in the treatment of an injury of the elbow-joint, was given judgment for the full amount of his claim with interest and costs in Judge Kenyon's court, October 25.

Diphtheria is increasing to an alarming extent at various points in the state. In Cleveland, 31 new cases were reported last week; in Youngstown, 32 cases have been reported, and in Columbus and Lima the disease is so prevalent as to bring prominently into notice the advisability of closing the public schools in the affected neighborhoods.

Newark Isolation Hospital.—The decision in the injunction proceedings against the Newark Board of Health, restraining it from establishing a hospital outside of the city, is that the smallpox hospital may be maintained north of Newark until the six patients confined therein shall have recovered. No new patients can be taken into the hospital there after October 25. If any cases occur after that date the Board of Health must provide a hospital for them within the corporate limits of the city.

PENNSYLVANIA.

The estate of the late Dr. Jeremiah S. Trexler, Kutztown, is valued at $100,000.

Scarlet fever has caused the closure of the Howellville school in Tredyffin township.

Staff Entertained.—The medical staff of Pittston Hospital was given a sumptuous game supper by Dr. John B. Mahon, president of the Hospital staff, October 27.

Hospitals Hampered by New Law.—The Presbyterian Hospital of Pittsburg and Allegheny is greatly overcrowded, and although it has a fund of $40,000 toward a new building it can not proceed with the work on account of the new state law relating to the building of new hospitals in cities. The same law has prevented the erection of the new United Presbyterian Hospital at Allegheny for which land valued at $100,000 was recently donated, and which already has funds in hand for the erection and maintenance of the institution.

Personal.—Dr. John J. Light, who spent the summer in post-graduate study at Johns Hopkins University, has returned to Schaefferstown.——Dr. Robert Lee Finn, Greenfield, who, rather than pay a fine, served a month in the Erie County Jail for illegal practice, and has returned to Greenfield and defiantly commenced practice, and now, as a result, he is to be tried on a similar charge at the next term of the court of quarter sessions.——Dr. Lloyd Sallade, Williamsport, has been appointed to the resident staff of the Scranton Hospital.——Dr. Horace B. Heysham has opened an office at Norristown.

Philadelphia.

President of German Hospital.—Mr. Herman Hessenbruch has been unanimously elected president of the German Hospital, vice John D. Laukenan, deceased.

A Convenient Location.—The site for the municipal emergency hospital to be erected is in the poor burying ground, in the new Camden Cemetery, where a similar hospital was erected during the last smallpox epidemic. Four buildings will be put up at once. It has not yet been decided whether or not to remove the present smallpox patients to the hospital, but any new cases that develop will at once be taken there.

Vaccination Urged.—At the last meeting of the Philadelphia Medical Society the following resolutions were adopted: "Whereas, smallpox is prevalent in the city of Philadelphia to an extent that warrants every precaution being taken to prevent an epidemic with the advent of cold weather; and, Whereas, we possess in vaccination an absolute safeguard against the disease; Therefore, be it resolved that the Philadelphia County Medical Society, representing the physicians of the City and County of Philadelphia, strongly indorse vaccination and urges upon every one not recently vaccinated to avail himself of the great protective power of this procedure."

TENNESSEE.

Cornerstone Laid.—The cornerstone of the new building for the Medical Department of U. S. Grant University, Chattanooga, was laid with appropriate ceremonies, October 29.

The Health of Memphis.—The twenty-second annual report of the Memphis Board of Health shows remarkable progress in sanitation. Within the last decade the death-rate has been yearly reduced. But in the report just issued the death-rate is 5 per cent. lower than during the previous year. There were but 35 cases of diphtheria with 5 deaths and 93 cases of scarlatina with 5 deaths.

Personal.—Dr. Michael Campbell, superintendent of the Tennessee Eastern Hospital for the Insane, has been unanimously re-elected for a term of eight years.——Dr. Clio B. Collier, of the staff of the State Hospital, Knoxville, has resigned and will locate in Washington.——Dr. Payne A. Tinsley, Dandridge, has succeeded the late Dr. James A. Harris as physician of Jefferson County.——Dr. J. B. Layman has opened an office in Knoxville.

State Board of Health.—The State Board of Health, which met recently at Nashville, heard Secretary Albright's report, which showed there had been in the state between April 1 and September 12, 2,059 cases of smallpox and 94 deaths. Of these cases 861 were white. Shelby and Davidson counties, the report says, are, for the first time in years, free from smallpox. Scarlet fever of a very mild type exists in a number of counties. A resolution was adopted pertaining to tuberculosis, anthrax and glanders, which are said to exist in several sections of the state among the lower animals. The resolution asserts that these diseases may be communicated to the human race, and gives notice that all persons are prohibited from selling milk or other dairy products intended for human food from cattle infected with these diseases.

GENERAL.

Ankylostoma Duodenale in Hawaii.—Executive Officer Pratt has issued a letter to each Government physician indicating the prevalence of severe cases of anemia (Egyptian chlorosis) due to the parasite ankylostoma duodenale. He suggests large doses of thymol, and that reports of its effect be sent to him in each case.

Precautions Against Plague Introduction.—The quarantine authorities of the United States and Canada are taking the necessary precautions against the introduction of the bubonic plague from the infected ports of Europe. The National and State officials will co-operate and exert every effort to prevent its introduction.

Manila Medical Society.—The new Society is meeting with opposition from the Collegio de Medicos y Pharmceuticos. The members of that school claim that no new medical society is needed. There is a so-called society of physicians and pharmacists already in existence, but it is claimed that there have been but two or three meetings of the body within two years, and then only for the purpose of discussing politics and not questions of importance to the profession with which the members of the society are supposed to be identified. It will be readily seen that a new medical organization is sadly needed. It is the intention of the new Society to hold semi-monthly meetings for the purpose of discussing questions pertaining to the practice of medicine and surgery. As a well-known army surgeon remarked: "When a Filipino graduates his studies are over. He does not keep abreast of the times. The physicians of Manila, outside of the Americans and one or two whom I have in mind, are many generations behind the times. They know practically nothing whatever regarding the modern practice of surgery and medicine. They have taken no steps to investigate the diseases of the tropics. Especially has this been the case in regard to dysentery. Very little is known regarding amebic dysentery, and what little is known has been discovered by American practitioners. If the local doctors had made a study of this disease ten years ago, there is no doubt that we would know how to cope with it successfully by this time." The new society will publish a monthly medical journal, in which will appear the proceedings of the Society at the various meetings as well as original articles by the members of the Society.

CANADA.

Smallpox has appeared at Winnipeg; over seventy cases have been reported at Ottawa.

Health Report of Toronto.—The following are the figures for contagious diseases for October: Typhoid, 16; scarlet fever, 69; diphtheria, 71.

Dr. R. O. Raymond, one of the oldest practitioners of Montreal, died last week. He was 74 years of age, and had been practicing in that city for fifty years. For some years he was the official physician of the Montreal gaol.

British Columbia Fears Smallpox.—Advice from Rossland dated October 29 states that considerable alarm is felt at many points near the international boundary line owing to the existence of an epidemic just across the border. Dr. Sinclair, the Dominion health officer for this district, has been advised of the outbreak and is having quarantine officers appointed to assist him in his work while the epidemic continues.

Incurable Children.—The annual meeting of the Toronto Home for Incurable Children was held last week. The annual report showed that the Home was progressing favorably. During the past year 6 children were admitted; and the number at present being cared for is 11. The treasurer's report showed

that donations to the extent of $1500 had been received during the year. The board of medical attendants was re-elected.

The Chinese vs. Health.—An action has recently been tried at Vancouver before the Chief Justice of British Columbia and a jury, brought by a chinaman against a health inspector for breaking into his house in the performance of his duty. The judge and jury upheld the action of the health inspector on the ground that the laws of the Board of Health with regard to "lodging houses" showed that the inspector was within his rights. The action was for $1000 damages.

Osteopaths and Christian Scientists.—Two trials are at the present time proceeding at Toronto, one against an osteopath and the other against a "christian scientist," the latter charged with manslaughter, his child having died without medical attendance, from diphtheria. In the case of the osteopath, an inquiry is being made into the death of a young woman in his office, who died suddenly, and who was undergoing treatment for a very large goiter.

Quebec Municipal Councils and Vaccination.—In consequence of outbreaks of smallpox multiplying in the Province of Quebec, the Provincial Board of Health has ordered that municipal councils shall see that industrial establishments shall require all persons in their employ to be vaccinated who are not able to show they were successfully vaccinated within the past seven years. The executive officer of all the municipal sanitary authorities has also been ordered to see that directors of all educational institutions shall satisfy the board of health that their charges have been successfully vaccinated.

Ontario September Deaths.—A short time ago the Ontario Board of Health sent out warnings to the clerks of the different municipalities cautioning them to make monthly health returns. The effect of this has been salutary, as for September, 99 per cent. of the population has been accounted for, which means that 770 out of 777 municipalities have been summed up. The total deaths for the month were 1959. This is an increase of 31 over August, but a decrease of 531 in comparison with September of 1900. The deaths from contagious diseases were as follows: Scarlet fever, 13; diphtheria, 45; measles, 2; whooping cough, 17; typhoid, 41; consumption, 165.

FOREIGN.

Surgeon-General W. Taylor, M.D., C.B., has been appointed Director-General of the British Army Medical Service.

Obituary.—The death is reported from St. Petersburg of Marcel Nencki, well known for his researches and discoveries in biologic chemistry and numerous contributions to medical literature.

New Schools of Tropical Science.—Germany has recently started a school for the study of tropical medicine, and the French government has decided on the establishment of two, in Paris and Marseilles.

Legacy for the University of Leipsic from Physician's Estate.—The widow of the late professor of the history of medicine at Vienna, Dr. Puschmann, has bequeathed her entire property, about a quarter of a million dollars, to the University of Leipsic.

Koenigsberg Medical Course Closed to Women.—The Königsberg medical course is nominally open to women, but three professors, Stieda, Lossen and Pape have closed their lectures to women students, which debars them from completing the course.

Cancer Research Endowment.—A fund of 500,000 marks has been presented to the city of Frankfurt, Germany, for an endowment for research in regard to the etiology of cancer. Ehrlich and Weidenreich have been entrusted with the task, the latter summoned from Strassburg for the purpose.

Bubonic Plague in Great Britain.—The three cases of plague in Liverpool are reported convalescent in hospital. It has appeared again in Glasgow, where there has been one death; there are now three suspects in the latter city found in a station hotel belonging to the Caledonian Railroad.

German Association for the History of Medicine.—Sixty persons interested in promoting the study of the history of medicine and the natural sciences, have organized an association for the purpose. The annual fee is ten marks. The treasurer is Dr. Emil Wohlwil, Hamburg. Dr. Peypers, of Amsterdam, editor of *Janus*, is one of the officers. The society will commence the publication of a periodical in 1902. Societies, institutes, libraries, etc., as well as individuals, are cordially invited to membership.

Special Article.

Fatal Results from Diphtheria Antitoxin in St. Louis.*

In reply to a request for information in regard to the deaths from antitoxin in St. Louis, Dr. Mac C. Starkloff, Health Commissioner of St. Louis, writes to THE JOURNAL under date of November 6: " . . . On the afternoon of October 26, I received a communication from a physician saying that he had under his observation two cases of tetanus which were undoubtedly caused by the diphtheria antitoxin furnished by the Health Department. I immediately ordered that the distribution of antitoxin be at once discontinued, and addressed a letter to Dr. Amand Ravold, our consulting bacteriologist, by whom our antitoxin is made, asking for information in regard to the production of antitoxin. I enclose a copy of his reply.

"Following the reports of death from tetanus claimed to have been produced by the antitoxin, I had a conference with Dr. R. M. Funkhouser, coroner, and an investigation was begun. Also a commission of expert pathologists, consisting of Drs. B. Meade Bolten, E. C. Walden and Carl Fisch, was appointed to make autopsies and examine the serum, a few bottles of which were found in the possession of several physicians.

"Up to the present date, as far as I have ascertained, there have been twenty cases of tetanus reported, following the use of our serum, with ten deaths. . . . The lot of diphtheria antitoxin labeled August 24 ran out on October 23, and the last dose of it was injected on October 24."

Report of the Bacteriologist.

The following is from the report of Dr. Amand Ravold, referred to above:

The horse from which the antitoxic serum labeled Aug. 24, 1901, was taken, was quartered at the Poor House stables. He was a bay horse, 16 hands high, weighed over 1600 lbs., and named Jim. Originally, he was an ambulance horse, had been injured in the shoulder, and was turned over to me by Dr. Jordan, chief dispensary physician, in 1898. He has been under treatment for the production of diphtheria antitoxin for nearly three years, has been bled a number of times and has furnished over 30,000 c.c. (30 quarts) of diphtheric antitoxin. In fact, the greater part of the antitoxin distributed by the Health Department during the years 1900 and 1901 came from this horse.

On August 10 he was inoculated with 800 c.c. of diphtheria antitoxin of a strength of 0.02. August 24, I bled him, taking 10,000 cubic centimeters (10 quarts) of blood. (The blood was kept in an ice chest 300 yards from the stable.) From this blood we obtained 2400 c.c. of serum, which was brought in from the Poor House, August 28 and 30. I personally added 0.4 per cent. tricresol to the serum, allowed it to stand for twenty-four hours, drew off 10 c.c. and tested it on six guinea-pigs to ascertain its antitoxic value. It was found to contain between 150 and 200 units to the cubic centimeter and was labeled 1500 units to 10 c.c. None of these guinea-pigs died either of dipntheria or tetanus, although the 200 unit pigs were sick for several days. It was bottled about September 10, and the distribution began. From that date until October 26 no other serum was given out to physicians.

From October 23 to 26 we ran out of serum. On October 18 Mr. Taylor called my attention to the fact that our serum was running low and that an unusual demand was being made for it. I gave instruction that not more than one bottle be given to any applicant until a new lot of serum could be obtained.

On September 22 I again injected Jim with 300 c.c. of strong diphtheria toxin, and on September 30 bled him, taking 8000 units of blood. On October 2 I was notified by telephone that Jim was sick, and Dr. Ellis, veterinarian of the Health Department, was sent out to see him. He pronounced the horse sick with tetanus and ordered him killed. The serum from the horse was sent to the City Chemist's laboratory October 8 or 9, while I was in Chicago; tricresol was put in it by my assistant, Mr. Schmidt. On my return, October 11, Mr. Taylor brought two flasks containing antitoxin, and said that it came from the Poor House while I was away. It was the serum from the dead horse. I emptied one flask and Mr. Taylor the

* This report was received after the editorial on this subject was on the press. The latest newspaper reports at this writing, Nov. 7, state that 13 deaths have occurred from the use of the antitoxin.

other into the laboratory sink. On October 26, we received information from Dr. Jordan that a case of tetanus was said to have been caused by the city antitoxin.

A search was made for some of the August 24 serum. Two bottles were found in the City Dispensary on Sunday, October 27, and turned over to Mr. C. A. Snodgras to search for the bacillus of tetanus. He will report to you when his investigation is completed.

A bottle of serum is in the possession of Dr. Johnson, of the dispensary staff, and one in your possession. I earnestly advise that one of the bottles of serum be given to Dr. E. C. Walden and the other to Dr. Meade Bolten, of this city to ascertain whether or not the serum contains the bacillus of tetanus or the toxins of tetanus. Both are bacteriologists and thoroughly reliable men.

Preparation of Antitoxin.—Our antitoxin is prepared as follows: For obtaining the diphtheria toxins, we inoculated a specially prepared broth with bacillus diphtheriæ No. 8 of Park, and grew it in an incubator at 37 C. for from eight to ten days. At the end of that time it is taken from the incubator; 0.4 per cent. of tricresol is added to it, and after standing for twenty-four hours is filtered through a porcelain filter. Small quantities are injected into guinea-pigs, in order to ascertain its toxic potency. If the toxin proves highly virulent, it is injected into horses in gradually increasing doses.

Strong, healthy horses are selected, free from glanders and tuberculosis; about once every ten days increasing quantities of toxin are injected subcutaneously into them; the site of the injection being the side of the neck or the loose tissue behind the shoulder blade. Here the hair is clipped short and the hide first washed with soap and water and then soaked with a powerful disinfectant, consisting of a 5 per cent carbolic acid solution containing one to 1000 corrosive sublimate and a 0.5 per cent of hydrochloric acid. The injection is made with a sterile syringe. When the horse can give large quantities of diphtheria toxin without producing decided elevation of temperature or other disturbances of health, he is ready to bleed. Our method is to shave a wide area along the side of the neck over the jugular vein; this area is thoroughly disinfected with the acid (carbolic acid solution mentioned above) and with a sterile knife an incision is made through the skin over the vein. A sterile sharp pointed canula with a rubber tube attached to it, is thrust through the incision into the vein beneath, and the blood flows through the tubes into specially constructed flasks, which have been steam serilized. The wound in the skin is stitched up and flexible collodion painted over it.

The blood put in an ice chest is allowed to clot, and when the serum separates, which takes several days, it is poured off and to it is added 0.4 per cent. of tricresol. After standing several days to "ripen" it is filtered through a sterile paper filter, and the filtered serum is mixed in definite quantities with ten times a minimal lethal dose of diphtheria toxin. The mixture is injected into guinea-pigs weighing 300 grams, to ascertain the quantity of serum which will keep the guinea-pig from dying; ten times that amount of serum is an antitoxic unit. The number of antitoxic units in one cubic centimeter is then calculated and the serum labeled. Upon the label is written the day of bleeding and the number of units to 10 c.c. of antitoxin.

Before distribution, the serum is again filtered and put into small sterile bottles, each containing 10 c.c. of serum and corked with a sterile cork stopper. A label upon it bears the date of the bleeding and the number of antitoxic units in the bottle.

I go to this length in explaining our methods to show the rigid aseptic precautions with which the whole procedure is surrounded. In regard to myself, I have personally selected every horse from which we have made antitoxin. I have given every injection which the horses have received since the beginning of the work. I have bled the horses throughout the whole period of the investigation, and, further, I have with very few exceptions tested every lot of serum which has left the laboratory.

Feeling keenly the very great responsibility which has rested upon me, I have been painstaking in my endeavors to produce a high grade of antitoxin serum, and have trusted no part of the procedure to anybody, except the preparation of the diphtheria broth, which my assistant, Mr. Martin Schmidt, skilfully makes for me, and the filling of the small bottles with serum, which is the work of our careful janitor, Henry Taylor.

The horse Jim seemed to be in perfect physical condition when I bled him on August 24 and September 30. The bleeding on September 30 was followed by a decided reaction; on the following day he refused food and began breathing with difficulty. Dr. Ellis pronounced him sick beyond recovery, with tetanus, and he was killed.

I feel confident that the tetanus bacillus will not be found in the serum, both from the painstaking care with which it is prepared and from the fact that it contains 0.4 per cent. of tricresol. It is, however, within the limit of probabilities that the horse may have had the tetanus bacillus latent, or slowly acting within him some time before August 24, and that the disease did not develop sufficiently to manifest itself until his vitality was lowered by the bleeding of September 30. If this were so, the tetanus toxin might have been in his blood on August 24, the date of the bleeding. If the tetanus toxins were in the horse's blood prior to August 24, it was beyond the range of human knowledge to detect it by an inspection of the animal.

It is a well-known fact that horses undergoing treatment for the production of diphtheria antitoxin are highly susceptible to infection with the bacillus of tetanus. We have lost six antitoxin horses with tetanus since 1895.

Very respectfully, [Signed] Amand Ravold, M.D.
City Bacteriologist.

Correspondence.

A Place to Clean the Teeth Needed in Railroad Car.

Pittsburgh, Pa., Oct. 28, 1901.

To the Editor:—Apropos of the much discussed question of the spitting nuisance, the attention of the managers of the sleeping car companies should be called to the practice of cleaning the teeth and spitting in the bowls of the washroom, in violation of every principle of decency, good taste and sound hygiene. A sign in conspicuous form and in unmistakable terms, should be placed in the lavatories of sleeping cars, positively forbidding spitting, cleaning the teeth or blowing the nose in the washbowls. Nothing more unpleasant can be imagined than to witness the actions of the unclean animal, as he performs his morning ablutions, brushing his teeth and spluttering and snorting over the bowl. One's gorge rises at the sight, when a person reflects that he must wash in the same place or forego the comfort of having the facilities of keeping clean. The thought of washing in a bowl into which the person who has preceded has deposited various secretions and vile impurities from his teeth, mouth, nose, throat and bronchi, would be quite enough to deter many persons from using the lavatories at all. It is not only the filthiness of it all, but the actual danger from this practice that calls for immediate correction. It is no imaginary evil when subjects of phthisis, nasal catarrh, ozena, bronchorrhea and syphilitic disease deposit the secretions from the mouth and nose into these receptacles.

Not long since, the writer witnessed one of the occupants of a sleeper taking his morning wash. He not only cleaned his teeth in a very painstaking manner over the bowl and blew his nose repeatedly into the basin, but to complete this part of his toilet, he took from his satchel a piece of whalebone in the form of a horseshoe, and placing this instrument across the posterior surface of the tongue, thoroughly scraped that member a number of times, the decomposed epithelium and debris from the dorsum of the tongue being deposited in the bowl, where he had already blown his nose, cleaned his teeth and cleared the secretions from his throat.

The cleaning of the teeth is a very necessary and important part of the morning toilet, and certainly the art that enters into the modern sleeping car can easily solve the simple problem involved in this necessity. The sleeping car is a veritable wonder of ingenuity, and provision can be made no doubt for the cleaning of the teeth, and afterwards no one should be permitted to use the bowls for such a purpose.

It is one of the unexplainable things, that this practice should ever have been tolerated; for the first man who blew his nose or expectorated into the receptacle where other people had to wash their faces, should have been ejected from the car.

Yours respectfully, Henry D. Fulton, M.D.

Report of Autopsy on Assassin Disclaimed.

NEW YORK CITY, Nov. 2, 1901.

To the Editor:—It has come to my knowledge that an account purporting to be a report of the autopsy performed upon the assassin Czolgosz has in a manner been placed upon the market and offered to various medical journals. To prevent other periodicals from being misled I beg to inform you that no authentic report has as yet been issued, and that none is authentic or reliable unless signed by Dr. Carlos F. MacDonald or myself, or both jointly. Since the alleged report is based upon a series of disjointed data dictated by me to a stenographer in whom I reposed confidence and who had no permission to give out any portion of it, it is necessarily valueless and unintelligible and possibly misleading. As may be readily understood, these notes were made as aids to the memory and to supplement other notes in my sole possession and hence are useless unless corrected and revised by myself.

Should it happen that any garbled rendition be published, Dr. MacDonald and myself will feel it necessary to repudiate and disclaim it. Very sincerely yours,

EDWARD A. SPITZKA, M.D.

Ether to Make Criminals Talk.

WEEHAWKEN, N. J., Oct. 30, 1901.

To the Editor:—Allow me to propose a new use of ether. In the case of condemned criminals, who refuse to talk and thus implicate their confederates, put them under the influence of ether in much the same way that patients are prepared for surgical operations. Ether, given in a certain way and quantity, will cause otherwise silent people to talk. While thus intoxicated with ether it is not unlikely that the criminal will give some clew as to his confederates. The ether should be carried only to the stage of stimulation, not of profound anesthesia.

At a time during the stage of stimulation the will power is in abeyance and the door of the mind is unlocked. When this period is reached the tongue is free to tell the most secret things. This stage may be prolonged for ten or twenty minutes, or for a longer time, by the judicious use of other stimulants. Very truly yours, ALBERT W. WARDEN, M.D.

Married.

C. E. DRAKE, M.D., to Miss Garnet Dumm, both of Zanesville, Ohio, October 24.

GEORGE THEODORE MUNDORFF, M.D., to Minnie Grau, both of New York City, October 30.

HARRY E. PETERMAN, M.D., to Miss Helen Louise Meyer, both of Baltimore, October 23.

E. M. WHITTEN, M.D., to Miss Georgia Weiner, both of Nebraska City, Neb., October 25.

C. T. ESTABROOK, M.D., to Miss Edith L. Tourtellotte, both of Worcester, Mass., October 24.

THOMAS C. BUSSEY, M.D., Texas, Baltimore County, Md., to Mrs. Augusta E. Gorman, of Baltimore, October 23.

ARTHUR CHAPMAN DOTEN, M.D., Worcester, Mass., to Miss Ethel Sturdivant Norton, of Portland, Maine, October 23.

Deaths and Obituaries.

William M. Hudson, M.D., Jefferson, 1855, died at his home in Hartford, Conn., October 30, aged 68. For the last twenty years he had been stockholder auditor of the New York, New Haven and Hartford Railroad Company and had held a number of important public positions.

E. L. Diefenderfer, M.D., University of Pennsylvania, Philadelphia, 1862, a prominent practitioner of Milwaukee, died at his home in that city, October 27, from malignant disease of the intestines, after an illness of a year and a half, aged 62.

John D. Dunning, M.D., University of Buffalo Medical Department, Buffalo, N. Y., 1852, died October 27, at his home in Webster, N. Y., aged 75. He was one of the charter members of the New York State Medical Association.

J. Mortimer Crawe, Sr., M.D., Jefferson Medical College, Philadelphia, 1859, the oldest practicing physician of Watertown, N. Y., died there October 29, aged 71. He was a member of the New York State Medical Association.

Dennis W. Porter, M.D., Rush Medical College, Chicago, 1878, who had practiced in Stonington and Blue Mound, but moved recently to Decatur, Ill., on account of ill-health, died at his home in that city, October 23.

Peter Hewetson, M.D., one of the oldest physicians of Ohio, who had practiced in Amanda, Ohio, for half a century, died at his home in that place, October 26, from heart trouble after a brief illness, aged 79.

R. D. Blackmore, M.D., University of Iowa, Iowa City, 1901, a surgeon in the employ of the Rock Island extension in Texas, died at the University Hospital, October 26, from typhoid fever, aged 27.

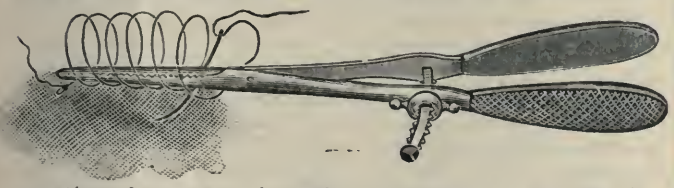
J. Arthur Fullenwider, M.D., Barnes Medical College, St. Louis, 1900, located in Champaign, Ill., died at St. Luke's Hospital, Chicago, after an operation for appendicitis, October 23, aged 25.

Robert T. Bush, M.D., New York University, 1865, died at his home in Gallatin, Tenn., October 27, aged 65.

Miscellany.

Reduction of Temperature by Continuous Irrigation of the Rectum.—A recent Geneva inaugural thesis describes the results of experiments on dogs to determine whether the temperature of the body can be influenced by double current irrigation of the rectum. Two urethral sounds were used for the purpose, with water at 75 F. The temperature in the axilla was reduced constantly in healthy dogs from two to nearly four degrees in the course of forty minutes of this irrigation. Further tests showed that the same results were attained whether the water was at the temperature of the body or above it and whether the irrigation was prolonged more or less than forty minutes. The results indicate that the influence on the temperature is of a reflex nature. In fourteen out of sixteen dogs rendered febrile by the subcutaneous injection of pus or putrid matters, the temperature was influenced the same as in the healthy dogs, with two exceptions. It returned to normal in all cases in the course of one or two hours. The double current irrigation proved perfectly harmless in all the numerous tests.

Pawlow's Latest Researches on the Digestive Processes.—Pawlow's researches on dogs provided with a gastric fistula made in such a way as to simulate natural conditions, have elucidated so many obscure points in our knowledge of the processes of digestion, that he was awarded the Nobel prize of $50,000 as recently announced in THE JOURNAL. His latest studies have established that the second or chyme period of digestion is induced by a reflex of gastric origin, and that the stomach possesses an auto-regulating mechanism. When a sufficient amount of hydrochloric acid has been secreted, it exerts an inhibiting action on the gastric secretion. His experiments for the study of the bile were on dogs with intact biliary passages. The portion of the intestine containing the orifice of the common bile duct was fastened to the abdominal wall, opening outward. He found that the flow of bile is intermittent, and that only fats, the products of the digestion of albumin and the extractives of meat have the power to induce the secretion of bile. He has also established that the bile has an inhibiting action on the gastric juice, while it promotes the action of the pancreatic juice and especially of the saponifying ferment in this juice. It, therefore, serves as an intermediary between the gastric and the pancreatic digestion. The pancreatic juice is the stimulant par excellence of the intestinal juices. He has also found that the reflex which regu-



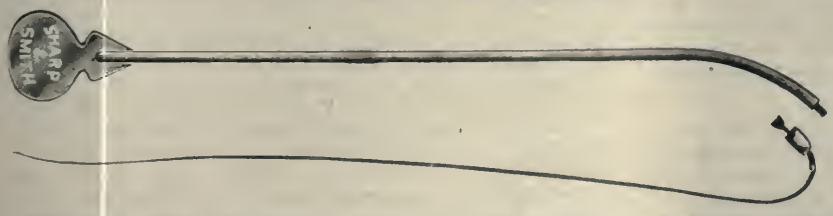
lates the passage of food from the stomach into the duodenum is of a chemical rather than a mechanical order. The reflex follows the entrance of the acid chyme into the duodenum. He was able to cause an alkaline solution in the stomach of a dog to be retained indefinitely by instilling diluted gastric juice or hydrochloric acid into the duodenum. The stomach emptied itself at once, if, instead of the acid, an alkaline solution was instilled. This mechanism is evidently designed to prevent the passage of too large amounts of gastric juice into the intestines, as its acidity would inhibit the action of the pancreatic juice. The ingestion of food has a similar inhibiting action on the evacuating movements of the stomach. They occur even during fasting, but cease after the ingestion of food for an interval long enough to allow it to undergo the necessary modifications. Application of irritants to the surface of the stomach induces an enormous secretion of mucus, free from pepsin, destined to protect the walls of the stomach and aid in the elimination of the irritating substance or render it harmless by a coating of mucus. The ingestion of meat stimulates exclusively the pepsin cells to activity.

New Instruments.

NEW PILE CLAMP.

RUFUS D. MASON, M.D.
OMAHA, NEB.

I wish to briefly describe a new pile clamp that I have had made and used with great satisfaction. This instrument is lighter and neater than those commonly used, and yet is strong enough to withstand all the pressure required. Being made with smooth, tapering jaws, it is adapted not only to pile



operations, but to any place where a clamp may be needed in abdominal or pelvic cases. The opposing edges of the jaws are notched to secure good holding qualities. The cut shows the method of using it in the continuous suture operation for piles. For cautery operations it is simply perfect.

AN IMPROVED METHOD OF ATTACHING A METALLIC SOUND TO A FILIFORM BOUGIE.

HENRY G. ANTHONY, M.D.
CHICAGO.

In the treatment of tight strictures it is frequently desirable to pass a metallic sound, catheter, or lithotomy staff attached to a flexible filiform guide rather than employ tunneled instruments or Bang's whalebone bougie.

The device now employed for attaching a filiform guide to any urethral instrument is the one used in Guyon's sound and

in Maisonneuve's urethratome. A metallic tip threaded onto the end of the filiform is screwed into the end of the sound. This method of attachment is insecure and unsafe. Cases are on record in which filiforms have become detached in the bladder necessitating surgical operation.

To obviate this danger I had the tip of a sound cut off and bored through so that after a filiform has been passed through the tip it may again be screwed onto the end of the sound. Only the best imported filiforms with large heads should be employed and the sounds should be of the Otis or Ultzmann curve.

A NEW ADENOID CURETTE.

W. STANLEY SAMSON, M.D.
LANCASTER, OHIO.

The accompanying illustration shows a new adenoid curette, constructed on different principles from other sharp or dull curettes used in adenectomy. The main shaft of the instrument is 14 centimeters long, attached to a pistol grip. Upon the shaft rests a slide with two rings for the index and second fingers. To the slide is attached a second shaft, by means of which the blade can be moved 45 degrees forward and backward when traction is made upon the rings. The blades, two in number, resemble the Gottstein blade in general conformation. The dull blade has no cutting edge; the horizontal portion is round and the size of a No. 16 piano wire.

The knife blade resembles the blade of the Gottstein curette very closely, excepting the knife, which is only 2 millimeters wide. The fenestra of each blade is 16 millimeters transversely and 20 millimeters longitudinally. The dull blade is to be used on soft growths and especially in children of but a few years; the knife blade is for tough and highly organized adenoid tissue. The cardinal feature of the instrument is that the shaft can be maintained at the same relative position, and the blade brought against the choanæ and then swept over the vault, embracing the largest growths; by greater traction on the rings the blade is brought against the pharyngeal wall and by an upward movement of the hand the cutting edge is carried as low as desired. The procedure may be repeated as often as necessary without removing the instrument from the nasopharynx. The instrument is aseptic, and the blades are interchangeable.

Book Notices.

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF GEORGIA. Fifty-second Annual Session. 1901. Atlanta, Ga.: Published by the Association.

The Secretary's report shows that the membership of this Association is 460 in good standing, with 150 on the list who are not in good standing, these being back in their annual dues. This represents about one in six of the regular members of the profession in Georgia who belong to the State Association. The report of the Committee on Medical Legislation is an interesting document. It illustrates the oft-repeated assertion that the profession wields a great political influence when it can be aroused to act. The osteopaths made a big fight for a bill in the Georgia Legislature and the committee representing the State Association sent out earnest and repeated appeals by mail and otherwise, urging the members of the profession to use their personal influence with the members of the Legislature. The result was noticeable and the osteopath bill was decisively beaten. The committee says: "It was pleasing in the highest degree to observe the power of the three thousand doctors of this State when fully aroused and united for a common purpose. This experience illustrates in a striking manner the potency of this influence when properly directed, and it is devoutly hoped that this object-lesson may not be underestimated or forgotten." We, too, hope that this object-lesson will not be forgotten, but we are afraid it will be. Committees in like work in other states during the last two or three years have had a similar experience to that of our friends in Georgia, but it can not be reiterated too often that when the medical profession unitedly uses its influence for any political purpose, it succeeds. The volume contains 32 papers read at the last meeting, together with the Constitution and By-Laws of the Association, the Code of Ethics of the American Medical Association, and a list of the members of the Medical Association of Georgia.

SURGICAL TECHNIC. A Text-Book on Operative Surgery. By Fr. von Esmarch, M.D., Professor of Surgery at the University of Kiel, and E. Kowalzig, M.D., Late First Assistant at the Surgical Clinic of the University of Kiel. Translated by Professor Ludwig H. Grau, Ph.D., Formerly of Leland Stanford University, and William N. Sullivan, M.D., Formerly Surgeon of U. S. S. *Corwin*. Edited by Nicholas Senn, M.D., Professor of Surgery at Rush Medical College. With 1497 Illustrations and 15 Colored Plates. Cloth. Pp. 866. Price, $7.00. New York: The Macmillan Co. 1901.

As its title indicates, this book is on technic only. As such, it has become recognized as the best in any language, and to the publishers, translators and editor, American and English surgeons owe a debt of gratitude. The translators have done their work well. Occasionally the peculiarity of the German idiom shows itself, but not often enough to mar the English, even for the most fastidious. No better man could have been selected to edit the work than Dr. Senn, and his additions in brackets add to its value. If we were asked in what this surpassed other works on surgical technic, we should reply: in recognizing the value of the smallest detail, in its wealth of practical illustrations, and in the conciseness and precision of its language. *Kurtz und buendig* was the motto adopted by the author in writing the original work in the first instance, which, by the way, was a prize essay. The book will prove to be the most valuable addition to English surgical literature of the year.

A TEXT-BOOK OF THE PRACTICE OF MEDICINE. By Dr. Herman Eichhorst, Professor of Special Pathology and Therapeutics, and Director of the Medical Clinic in the University of Zurich. Translated and edited by Augustus A. Eshner, M.D., Professor of Clinical Medicine in the Philadelphia Polyclinic. Two octavo volumes of over 600 pages each; over 150 illustrations. Price, per set, Cloth, $6.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

Dr. Eshner has done good service to English-speaking readers in his translation of this standard text-book of that distinguished German author, Eichhorst. He has made additions and annotations where it seemed advisable. The two-volume form in which the book appears does not lessen, but rather adds to its value, as the two single volumes are more convenient for use than one large one would be. The translation appears to be excellent, though once in a while we see a slip. We do not know whether to give credit to the translator or not for a confusion of the animal and vegetable kingdom on page 395; the statement that "hemoglobinuria has been noticed after ingestion of fungi, particularly mussels," strikes us as odd. This, however, is a minor matter and does not affect the general excellence of the work. The editor has introduced a number of illustrations, replacing or supplementing those in the original text, which add to its value.

INTERNATIONAL DIRECTORY OF LARYNGOLOGISTS AND OTOLOGISTS. By Richard Lake, F.R.S.C., England. Published under the auspices of The Journal of Laryngology, Rhinology and Otology, Rebman, London. 1901.

This little book contains the names and addresses of practitioners engaged in the study and practice of Laryngology and Otology and is intended to cover Europe, Africa, Asia, Australasia and North and South America. This is the second and an enlarged edition. It contains many names, but unfortunately has not been edited with sufficient care to enable one to distinguish between those who have a good standing in the profession as Laryngologists and Otologists and many others who pose in this light without sufficient qualification. However, it serves a most useful purpose in giving us the correct names and addresses of those whom we know by their writings. It is manifestly impossible to make such a directory perfect. We may, therefore, commend the author for what he has accomplished, while hoping for something better in another edition. If the author had indicated by reference, letters or numbers, all the society affiliations of each physician named it would have given the reader a fairly good idea of their professional standing and it would not have materially increased the size of the book.

SURGICAL EXPERIENCES IN SOUTH AFRICA, 1899-1900. Being Mainly a Clinical Study of the Nature and Effects of Injuries Produced by Bullets of Small Caliber. By George Henry Makins, F.R.C.S., Surgeon to St. Thomas' Hospital, London. Cloth. Pp. 493. Price, $4.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

This work is a valuable contribution to military medicine. The author has utilized his experience most thoroughly and it would be hardly possible for any surgeon who has to deal with gunshot traumatisms, and especially military surgeons, not to derive benefit from its perusal. It seems to us one of the most valuable medical contributions that has appeared upon recent military operations. The book is elegantly illustrated, and gracefully written. The author gives illustrations of the various missiles, showing some taken from captured cartilages that have evidently been tampered with to make the wound more deadly. He does not, however, credit all the accusations that have been made as to the use of explosive bullets. The treatise is one that will be likely to be referred to by almost all military surgeons, at least while gunshot wounds are caused in war or until methods have changed in a way that we can not at present conceive.

A HANDBOOK OF PATHOLOGICAL ANATOMY AND HISTOLOGY, with an introductory Section on Postmortem Examinations and the Methods of Preserving and Examining Diseased Tissues. By Francis Delafield, M.D., LL.D., Professor of the Practice of Medicine, College of Physicians and Surgeons, Columbia University, New York, and T. Mitchell Prudden, M.D., LL.D., Professor of Pathology and Director of the Department of Pathology, College of Physicians and Surgeons, Columbia University, New York. Sixth Edition with 13 Full-page Plates and 453 Illustrations in the Text in Black and Colors. Cloth. Pp. 819. Price, $5.00. New York: Wm. Wood & Co. 1901.

This excellent work has long been a standard and each succeeding edition makes its popularity among medical students, whether young or old, more secure. The present issue has been produced under the supervision of the junior author, Dr. Delafield having retired from an active share in its preparation.

To keep the work well abreast with advancing knowledge, some of the chapters have been entirely rewritten and every part, where necessary, has been revised so as to bring the subject matter well up to date. Many new illustrations have been added and evidently great pains have been taken on the part of both author and publisher to make the work as perfect as possible in every detail.

A Text-Book of the Practice of Medicine. By James M. Anders, M.D., Ph.D., LL.D., Professor of the Practice of Medicine and of Clinical Medicine, Medico-Chirurgical College, Philadelphia. Fifth Edition, Thoroughly Revised. Cloth. Pp. 1297. Price, $5.50 net. Philadelphia and London: W. B. Saunders & Co. 1901.

Dr. Anders is to be congratulated on the fact that five editions of his text-book have been called for in less than four years. The reason for this popularity is that the book is written with a full grasp of the necessities of the general practitioner. The latter has found it to be just what he wants, not only in that it covers the various subjects fully in detail, but because the general plan is such that reference to any phase of the subject is easily and readily made. In this new edition the whole work has been brought fully into harmony with the present known facts and recent developments in medicine. Several chapters have been rewritten and some new subjects introduced.

Atlas and Epitome of Special Pathologic Histology. By Docent Dr. Herman Dürck, of the Pathologic Institute of Munich. Edited by Ludvig Hektoen, M.D., Professor of Pathology in Rush Medical College, Chicago. Vol. II. Liver, Urinary Organs, Sexual Organs, Nervous System, Skin, Muscles, Bones. With 123 Colored Illustrations on 60 Lithographic Plates. Cloth. Pp. 192. Price, $3.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

This is another of the series known as "Saunders' Medical Hand-Atlases," books which have been well received by the medical profession of this country. This one on special pathologic histology is no exception to the other books of the series, which are practical and well illustrated expositions of the subjects treated. That the editor of the work is Dr. Ludvig Hektoen is sufficient to prove that from a scientific point of view the work is thoroughly reliable, up to date and in accordance with present known facts. The illustrations are very numerous, and all excellent.

The Ready Reference Handbook of Diseases of the Skin. By George Thomas Jackson, M.D., Chief of Clinic and Instructor in Dermatology, College of Physicians and Surgeons, New York. With 80 Illustrations and 3 Plates. Fourth Edition, thoroughly revised. Cloth. Pp. 642. Price, $2.75. New York and Philadelphia: Lea Brothers & Co. 1901.

This fourth edition of Jackson's diseases of the skin appearing in eight years of the first, shows its acceptability and in its present form it will be no less a success. The plan of alphabetical arrangement is a convenience to the reader and it forms one of the most handy text and reference books that we have seen. A number of new articles have been added on subjects not included in former editions, amongst which are acne keratosa, acne urticata, carate, craw-craw, endothelioma, etc. The illustrations are much the same as in the former works and call for no special mention.

Obstetric and Gynecolcgic Nursing. By Edward P. Davis, A. M., M.D., Professor of Obstetrics in the Jefferson Medical College, Philadelphia. Illustrated. Pp. 402. Price, $1.75. Philadelphia and London: W. B. Saunders & Co. 1901.

In the admirably clear way observed in his previous literary work, Dr. Davis takes up systematically the details of obstetric and gynecologic nursing, never invading the domain of the physician, but giving minute directions for the guidance of the nurse in normal and abnormal pregnancies, obstetric emergencies and the principal gynecologic operations. In an appendix a dietary with full directions for the preparation of foods is given, and also the methods of preparing surgical supplies and the methods and precautions of the Philadelphia Hospital. The book is satisfactorily illustrated and will be of value to all obstetric and gynecologic nurses, both in hospital and private practice.

Anesthetics and Their Administration. A Text-Book for Medical and Dental Practitioners and Students. By Frederic W. Hewitt, M.A., M.D., Cantab., Anesthetist to His Majesty the King. With Illustrations. Second Edition. Cloth. Pp. 528. Price, $4.00. London and New York: Macmillan & Co.

While this is stated to be a second edition, it is to all intents and purposes a new book. As it treats on general anesthesia only, the Schleich infiltration anesthesia, the various local anesthesias and spinal anesthesia are not mentioned. The information on the subject up to date is clearly and succinctly presented. The author considers the abolition of the stage of excitation the most valuable step in the evolution of anesthesia. Like most of the English authors, he advocates closed ether anesthesia, nitrous oxid and ether anesthesia.

Physicians' Clinical Chart and Fee Book. By Walter Key, M.D., Pilger, Neb. Leather. Price, $1.00.

This is a combination clinical chart and fee register, affording the practitioner not only opportunity for close study of the progress of his patients, but also a source of future reference, which is of no slight importance to the progressive physician. It is to be hoped that the copy for this excellent little book in future editions will be more carefully revised, and the proofs more critically read.

Urinary Diagnosis and Treatment. By John W. Wainwright, M.D., Member of the American Medical Association. Cloth. Pp. 111. Price, $1.00. Chicago: G. P. Engelhard & Co. 1900.

Dr. Wainwright's little book discusses, in addition to the material usually found in hand-books of this kind, the clinical significance of urinary findings and their practical application to the treatment of the diseases of which they are symptomatic.

Societies.

COMING MEETINGS.

Oklahoma Territory Medical Association, Oklahoma City, Nov. 13, 1901.

Southern Surgical and Gynecological Association, Richmond, Va., Nov. 12-14, 1901.

Tri-State Medical Association of Mississippi, Arkansas and Tennessee, Memphis, Tenn., Nov. 19-21, 1901.

Western Surgical and Gynecological Association, Chicago, Dec 18-19, 1901.

Oklahoma Territorial Medical Association.—The autumnal session of the ninth year of this Society will be held at Oklahoma City, November 13.

The Fifth District Branch of the New York State Medical Association will hold a meeting at the Palatine Hotel, Newburg, at 2 p. m., November 20, to which the members of the Association and the profession generally are invited.

Union District Medical Association of Indiana and Ohio.—At the annual meeting of this Association held in Connersville, Ind., October 24, the following officers were elected: Dr. Samuel C. Thomas, Rushville, Ind., president, and Dr. Everett R. Beard, Liberty, Ind., secretary and treasurer. The next place of meeting is Liberty, Ind.

Military Tract (Ill.) Medical Society.—The annual meeting of this Society was held in Macomb, October 24 and 25. The following officers were elected: Dr. Robert A. Kerr, Peoria, president; Drs. George E. Luster, Galesburg, and James E. Coleman, Canton, vice-presidents, and Dr. Charles B. Horrell, Galesburg, secretary and treasurer.

Central Illinois District Medical Association.—The twenty-seventh semi-annual meeting of this Association convened at Pana, October 29. The following officers were elected: President, Dr. T. L. Catherwood, Shelbyville; vice-presidents, Drs. E. J. Brown, Decatur, and George W. Fringer, Pana; treasurer, J. H. Miller, Pana; and secretary, C. R. Spicer, Taylorville. The next meeting will be held in Pana.

Medical Society of the Woman's Medical College (Baltimore).—The annual meeting of this Society was held, October 22, and the following were elected officers: Dr. W. Milton Lewis, president; Dr. Louise Erich, vice-president; Mary Cook, recording secretary; Henrietta M. Thomas, corresponding secretary; Jennie Browne, treasurer. The annual address was delivered by Dr. E. F. Cordell on "The Hartford Medical Society, 1797-8."

NEW YORK STATE MEDICAL ASSOCIATION.

Eighteenth Annual Meeting, held in New York City, Oct. 21-24.

The President, Dr. John A. Wyeth, in the Chair.

FIRST DAY, MONDAY.

At the meeting of the Council and Fellows on the first day, routine business was transacted, and the following officers elected: Dr. Alvin A. Hubbell, Buffalo, president; Dr. W. H. Biggam, Brooklyn, vice-president; Dr. Guy D. Lombard, New York, secretary; Dr. E. H. Squibb, Brooklyn, treasurer; Dr. Irving S. Haynes, New York, chairman of the Committee on Arrangements; Dr. E. Eliot Harris, New York, chairman of Committee on Legislation; Dr. J. W. S. Gouley, New York, chairman of Committee on Library; Dr. Alexander Lambert, chairman of Committee on Public Health and Medical Charities; Dr. J. Riddle Goffe, chairman of Committee on Publication; Dr. C. E. Quimby, New York, chairman of Committee on Nominations.

SECOND DAY, TUESDAY.

Correction of Deformities Following Osteitis of the Knee.

DR. WISNER R. TOWNSEND, New York, said that the application of force under anesthesia would correct most cases. Excision had been largely superseded by osteotomy, but a cuneiform osteotomy was only indicated in cases of marked deformity.

Appendiceal Fistula.

DR. JOHN B. DEAVER, Philadelphia, read this paper, and pointed out that such fistulæ constituted a preventable sequel to appendicitis operations, and that prevention was to be brought about by always operating on appendicitis at an early stage. Where the discharge consisted almost entirely of mucus it pointed to the appendix having been left behind and being connected with the fistula. Fecal fistulæ of the large bowel were more apt to heal spontaneously than those of the small bowel. For simple non-fecal fistulæ, a search should be made for the foreign body, all drainage should be removed and washing out of the fistula discontinued. Where a section was required, as was often the case in fistula of the small bowel, he preferred to do an end-to-end anastomosis by intestinal suture.

DR. DE LANCEY ROCHESTER, Buffalo, stated it to be his present belief that operation should be done in every case of appendicitis so soon as consent could be obtained.

DR. FREDERICK HOLME WIGGIN, New York, counseled greater thoroughness in operating, making it a point to systematically remove all the diseased tissue. Too often the appendix was left behind. It was well that the author had cautioned against a very common though senseless practice, i. e., persistent irrigation of these fistulæ. Many cases of fistula had been indefinitely prolonged by this thoughtless practice.

DR. E. D. FERGUSON, Troy, cited some cases in support of the position he took, that prompt operation should be the rule.

DR. GIBBON, Scranton, Pa., took a still more advanced position, and declared that the proper time to operate was before there had been any appendicitis.

DR. S. BUSBY ALLEN, New York endeavored to chill the rising enthusiasm of the surgeons present by the statement that about as many persons recover under the medical as under the surgical treatment.

DR. PARKER SYMS, New York, said that even admitting for the sake of argument that 80 per cent. recover under the medical treatment of appendicitis, this was nothing to be proud of, in view of the fact that, at the present day, the mortality attending early operations for appendicitis is almost *nil*. For the existing prejudice against operating in appendicitis medical men rather than the laity were responsible.

DR. J. R. STURTEVANT, Theresa, said that as a country doctor he wished to cast his vote for the early surgical treatment of this disorder.

DR. ALLEN A. JONES, Buffalo, also spoke of the advantages of operating, either immediately or in the interval between attacks.

DR. JOHN EDWARDS, Gloversville, seeing that the surgeons were having things too much their own way, put in a plea for what he called "the calomel treatment" of appendicitis. This consists in the administration of small doses of calomel throughout the attack, together with the avoidance of morphin.

DR. C. B. TEFFT, Utica, said that as the cause of appendicitis was to be found in the appendix, and thorough treatment demands the removal of the cause of a disease, he could not escape from the conviction that the successful treatment of appendicitis must be surgical. Any of the alleged cures under medical treatment had been temporarily relieved; they had not been permanently cured.

DR. ALFRED T. LIVINGSTON, Jamestown, spoke of the great harm done by the use of morphin, and pointed out that, unlike a proper remedy, it baffles instead of assisting Nature.

The Electrophone as an Aid to Deafness.

DR. SAMUEL G. TRACY, New York, exhibited this instrument, which he had devised. It consists essentially in a combination of the microphone and telephone, and is intended as a convenient and useful substitute for the ear trumpet and the conversation tube. It would prove useful in about 80 per cent. of cases of chronic catarrhal deafness, and in a few other forms of deafness.

Symposium on Malignant Growths.

DR. ALBERT E. WOEHNERT, Buffalo, read a paper on "The Clinical Course of Cancers, with Reference to Their Resemblance to Inflammatory and Infectious Processes." He spoke of the part played by environment, and pointed out that metastasis often occurs early. The more rapid the growth the greater the leucocytosis, and the greater the toxemia.

DR. GEORGE BLUMER, Albany, "The Present Status of the Infectious Theory of Malignant Neoplasms," described the so-called cancer parasite, and the many interesting experiments made in this field, together with the claims made by well-known investigators, but held that no one had yet been able to successfully cultivate an organism from malignant growths. The tumors that had been said to result from certain inoculation experiments were not true tumors at all, but only granulomata. There were many facts, he said, suggestive of the infectious origin of malignant neoplasms, but such origin was far from having been proved.

DR. ALEXANDER LAMBERT, New York, in a paper on "Intrathoracic Growths," said that intrathoracic growths are usually malignant. Malignant growths of the pleura are usually secondary, and give rise to a hemorrhagic pleuritic exudate. Carcinoma of the lung is more commonly primary, and is seven times more frequent than sarcoma. The symptoms are dyspnea and pain, often accompanied by currant-juice sputum. Expectoration and fever are less than in pulmonary tuberculosis. Sarcoma is more frequent than carcinoma in the mediastinum. They are often associated with a peculiar paroxysmal cough, which is almost pathognomonic.

DR. JAMES EWING, New York, considered "The Estimation of the Malignancy of Tumors with Reference to the Reported Cures of the Disease," and directed attention to the necessity, in reporting cases of cancer, to sharply distinguish between the different varieties. It was now well known that certain forms of cancer are almost certain to return regardless of the radical nature of the operation. Cancers having their origin in the skin of the breast are decidedly less malignant than other forms of cancer of the breast. It was best to base a prognosis on the age and rapidity of growth of a given tumor. Adenocarcinomata are often radically cured by the surgeon's knife. Malignant tumors springing from the lining cells of the lacteal ducts are apt to be very insidious in their course, and are rather slow of growth. True carcinomata are most malignant when occurring during lactation.

DR. ANDREW R. ROBINSON, New York, in a paper on "The Treatment of Carcinomatous Growths by Caustics," spoke of cutaneous epitheliomata. After speaking of the necessity for destroying all the cancer cells lest the partial removal serve only to increase the rapidity of growth, the author described the action of some of the caustics that had been used for the destruction of cancer, notably chlorid of zinc, caustic potash

and arsenious acid. He preferred the last because of its attacking pathological in preference to normal tissue. This agent was particularly well suited to the treatment of cancers of the face, as it causes less disfigurement than the knife, and is less apt to be followed by a recurrence.

Dr. Joseph S. Gibb, Philadelphia, presented a paper on "Malignant Disease of the Nose and Accessory Cavities." He said that sarcoma of the nares was more common among males and that no period of life was exempt. Carcinoma, unlike sarcoma, spreads quite rapidly into the sinuses, and pain is an early and characteristic symptom. Surgeons were disinclined to operate on carcinoma of the nose.

Dr. James P. Tuttle, New York, discussed the topic of "Cancer of the Large Intestine." He said that next to the rectum the cæcum was the most frequent site for malignant disease in the large bowel. The principal methods of treatment were three, viz., 1, excision; 2, enterostomy, and 3, entero-anastomosis. The first method gave the greatest prolongation of life, being about two years, while for enterostomy the period was nine or ten months, and for entero-anastomosis seven or eight months. The last gave the lowest immediate mortality.

Dr. Henry H. Morton, Brooklyn, described in a paper on "Malignant Disease of the Penis," the symptoms and the technique of the two operations commonly done for this condition.

Dr. S. Sherwell, Brooklyn, speaking of the use of caustics, said that he preferred to use the acid nitrate of mercury, applying it after curetting and cocainization. It should be neutralized with bicarbonate of soda after about twenty minutes.

Dr. Stephen Smith, New York, spoke of a very favorable experience he had had with cancers treated by the application of anhydrous sulphate of zinc.

Dr. John A. Bodine, New York, advocated the use of arsenious acid, applied preferably in the form of a paste composed of two parts of this acid and one part each of orthoform and gum acacia.

The Daily Medical Inspection of Schools.

Dr. Frederic W. Loughran, New York, spoke of the advantages of such inspection, and described the method employed by the health department of New York City.

Dr. James Lee, New York, said that this most excellent work should be broadened until it included the investigation of the sanitary condition of school buildings, the state of the special senses, and the fitting of the school work to the health and strength of the individual pupil.

Ethyl Bromid and Ethyl Chlorid Respectively as Surgical Anesthetics.

Dr. S. Ormond Goldan, New York, presented this communication. He said that these agents were not, in his opinion, superior to nitrous oxid, and their use as a preliminary to chloroform was unnecessary and dangerous. They should not be given except with the patient recumbent.

Dr. James P. Tuttle, New York, said that ethyl chlorid had been administered in New York City about two thousand times for anesthesia, without a single death or serious symptoms. It was best given on the old chloroform inhaler. It was especially adapted for use with alcoholic subjects.

Dr. Lucius W. Hotchkiss, New York, reported a case of "Perforation of Gastric Ulcer, with Report of a Case," in which he had operated successfully sixty hours after the occurrence of the perforation.

Dr. Frank W. Dennis, Unionville, in a paper on "The Therapeutic Value of Alcohol as Understood at the Beginning of the Twentieth Century," presented a mass of carefully selected statistics, all tending to show the evil effect of alcohol, and emphasizing the physician's responsibility when prescribing this agent.

Dr. A. Brothers, New York, read only a portion of his paper on "Pelvic Inflammation in the Female; Its Diagnosis and Management by the General Practitioner." He emphasized the importance of making the presence of pus the dividing line between medical and surgical treatment.

Dr. Grover W. Wende, Buffalo, under the caption of "Skin Diseases of Special Interest," presented an interesting series of photographs illustrating prominent cutaneous affections.

(To be continued.)

SAN FRANCISCO COUNTY MEDICAL SOCIETY.

Regular Meeting, held Oct. 8, 1901.

Dr. George H. Evans, in the Chair.

Present State of the Bottini Operation, with Special Reference to Personal Experience.

Dr. M. Kretoszyner thought the best time to operate was in the first stage of prostatism where distressing symptoms of frequent urination were setting in, and where cystoscopic examination demonstrated the beginning trabecular bladder. Whenever under such conditions we had to leave our patient to self-catheterization, where the slightest error in asepsis would expose him to all the dangers of an ascending urinary infection, then and there was the time for the Bottini. Here, with strict asepsis, we could perform the operation without any particular danger to, and with the greatest benefit for the future of the patient. Careful preparation, however, was always necessary, during which time local and internal treatment should be carried out, and careful local examinations made. He considered cystoscopy a necessary preliminary procedure without which we should only operate in exceptional cases. Whenever cystoscopy could not be successfully performed, and we were placed before the alternative of operating in the dark, he would then prefer to open the bladder from above.

The technic was considered in detail and the necessity of careful after-treatment urged. He had operated upon 26 patients with 3 deaths. One died from general sepsis; the second, ten days after operation, the postmortem examination demonstrating a far advanced interstitial nephritis; and the third died three days after the operation with acute uremic symptoms. Eleven of his patients had regained normal urinary functions. Six had materially improved; their general health and bladder function had been very much benefited by the operation, but they still had a residual urine of from 4 to 8 ounces and they still had to use a catheter once or twice daily. In 4 patients he could see no perceptible improvement, although they were operated on and treated with the same care as the successful cases. The two remaining cases were young men suffering from purulent prostatitis after gonorrhea. In both cases he made three incisions with the result that no more pus could be pressed out of the gland and all distressful symptoms had disappeared in both of these cases, however, almost complete incontinence followed the operation, which, in one case (three months after the operation) had partially improved. While refraining from formulating conclusions as to the real merits of the operation, he thought that it had come to stay and that the terrible suffering of old men from this condition would be effectually lessened by the procedure.

Perineal Prostatectomy.

Dr. George Goodfellow read a paper in which he described the technic which he thought was original as follows: The patient is placed upon his back with the thighs flexed on the abdomen (an exaggerated Simon position), a median incision is made, the membranous urethra and bladder entered. The finger is then introduced, pressure above the pubic bones made with the other hand, which permits the viscus to be drawn as far as desired toward the external opening. The enucleation is then made easy, and can be done very rapidly, the resulting hemorrhage amounting to almost nothing. After-treatment is simple, consisting of daily irrigation of the bladder with passage of good-sized sounds for ten days to two weeks in cases where the condition of the bladder demands such action. In uncomplicated cases, within forty-eight hours a part of the urine will be passed per urethram, and no further treatment is called for other than the introduction of sounds until all danger of contraction is over. It will be seen that

the operation just described is precisely what it purports to be: prostatectomy through a perineal incision; and, from the results, well worthy further trial. The author claimed that by means of this position and this method, with bi-manual manipulation, the neck of the bladder could be brought to the perineum without trouble, and the entire interior of the bladder as thoroughly explored with the finger as the interior of the uterus under similar circumstances.

Palliative Treatment of Chronic Prostatic Hypertrophy.

DR. JOHN C. SPENCER read a paper on this subject which he divided into general, medicinal and mechanical. Under the head of general treatment he included all that pertains to a maintenance of the best possible physical condition of the patient. Drugs, he thought, were only useful as placebos. Under the head of mechanical treatment there were comparatively few resources of a strictly non-operative nature at our command. Those cases where the amount of residual urine was small, the bladder being clean, required no treatment whatever; those suffering from occasional ischuria, with larger amounts of residual urine, must be catheterized from one to four or five times daily. He thought it might be possible to effect a slight reduction in the size of the gland by judicious massage, particularly in these cases where there is a catarrhal condition in the ducts and acini of the gland added to the hypertrophy; another procedure which sometimes gave relief to ischuria, was judicious dilation of the vesicle neck. He thought it was only by the most painstaking attention to these and many other details, individual to each case, that we might be able to make life tolerable to such sufferers as were denied relief through some radical operation.

PROFESSOR VINCENZ CZERNY of Heidelberg, who was the guest of the Society that evening, opened the discussion on these papers. He said that it was difficult for him to open the discussion on this valuable subject, but was very thankful it had been possible for him to note the experience of his colleagues here in the Society. He thought the subject was a large one, as it was treated to-day. The conservative treatment of the prostatic enlargement in the first place would be necessary, much as he had been fond of the radical course of extirpation. He had made several extirpations this year, the first of these was interesting as it was a subject 60 years of age, on whom he had made the suprapubic incision and extirpation of the projecting part of the gland on three different occasions; he had always come back as the enlargement returned. The first specimen of this extirpation was cancerous, he thought, but the examination showed it to be adenoid tissue; he finally extirpated by a semilunar incision in the perineum, in the same position described in Dr. Goodfellow's paper. A catheter was left in ten or twelve days and in five or six weeks he could urinate every two or three hours and only a very few drops of urine came through the fistula. The extirpation of cancer was a much more dangerous procedure because it was necessary to take out the capsule. The technic was much more difficult and the hemorrhage was great. He thought the Bottini was indicated where a valvular projection of the gland existed obstructing urination. It was not always easy to make the diagnosis and the cystoscope was not easy to use.

DR. G. CHISMORE said that the results of his observations with some experience in the treatment of the trouble which ensued had led him to be conservative in prostatic surgery; that conservative opinion had been of late much disturbed by the successful results obtained by Dr. Goodfellow as set forth to-night. He thought the liability to infection was less in the perineal than the suprapubic route. He thought the method of operating would be improved somewhat in technic, and we would eventually say to a man coming to us with senile hypertrophy: "Sir, have your prostate removed and you will be well." He had seen one or two good results from the combined suprapubic and perineal operation, but no case as yet with a perfectly satisfactory result from that procedure.

DR. R. L. RIGDON said he was sure all had been much pleased to listen to the papers and have the pleasure of the discussion given by Prof. Czerny and Dr. Chismore. It was evident that the operation on the prostate must go through the same evolution as the operations on the other parts of the body before we arrived at a conclusion at all definite and accepted by everyone. First, with Dr. Goodfellow's paper, he was much interested in the statement that the Doctor had no difficulty with a finger three inches long to enucleate the whole prostate if necessary. He had been through the perineum a number of times, for one reason or another, and found that it was difficult to reach the bladder, and in a case on which he made an autopsy, but which was not operated on for prostatic hypertrophy, but in which there was prostatic trouble, he was quite sure it would have been impossible for him to enucleate it even if he had pressed down on the pubes. He was glad that Dr. Goodfellow had such excellent results, but the method of operating should be tried further. With this operation he thought we would come across cases in which it would be impossible to reach the growth. He was satisfied that the perineal route was better than the suprapubic because of improved facilities for drainage. In regard to the Bottini operation, he had been skeptical about it and only recently had been lead to look with some favor on the operation judging from the results published. He had noticed in the paper read to-night by Dr. Krotszyner that the Doctor operated on 26 cases, 3 cases died and 2 had a fistula, therefore we have a bad result in about 20 per cent. of cases; still, Bottini's operation presented some favorable features, but we must confess it was not an ideal operation. He believed the conservative treatment in many of these patients would give better results than the radical work.

DR. E. E. KELLY said he had seen one of these operations of Dr. Goodfellow and it was well to emphasize two or three points that would overcome the objection raised by Dr. Rigdon. First, the position of relaxing all the abdominal muscles, and he was certain from the case he saw he could easily have brought the neck of the bladder to the surface and explored. Another thing was the celerity with which it was done, not more than five minutes of actual work and this was of great importance in elderly men where an anesthetic was an element of danger. Another thing in regard to the operation was that it was free from hemorrhage. The hemorrhage was exceptionally small and he believed that the Doctor stated that he never had to apply a ligature to check the hemorrhage. He was certain it would supersede the Bottini and it could be undertaken at an early period.

Case of Prostatic Calculus Removed Through a Perineal Incision.

DR. C. G. LEVISON said the patient was 35 years of age, gave a history of cystitis of gonorrheal origin, of 7 years' standing, during which time he had consulted a number of physicians. He complained of great perineal pain, vesical tenesmus, and frequent micturition, pain in the back, etc. The urine contained quantities of pus; chemical examination revealed traces of albumin due to pus; no serum albumin. Microscopic examination revealed quantities of pus and epithelial cells. Neither blood nor tubercle bacilli could be demonstrated. Harris' segregator collected clear urine from both ureters. In consequence of these examinations it was felt that the pus was of vesical origin. The cystoscope revealed a picture such as is usually seen in the hypertrophy of the aged. Metallic sounds introduced into the urethra did not come in contact with a stone, excluding the adventitious calculus. Rectal examination revealed an enlarged prostate, with indurated lobes. The right lobe was found to be the size of a pigeon's egg. Palpation revealed a middle lobe, with a smooth surface, producing the impression as if a stone lay embedded in the prostatic substance. Repeated examination made the diagnosis more probable. Firm pressure upon this part of the gland caused less uneasiness than when a normal prostate is manipulated. The patient himself could recognize when the finger passed over this indurated region. Massage of the prostate expressed less secretion than normal. Diagnosis of concretion of the middle lobe of the prostate with hypertrophy of the lateral lobes of inflammatory origin, was

made, and removal of the stone was advised, for it was felt that the stone was an active factor in the causation of the perineal pain and tenesmus. The operation was carried out as follows: With the patient in the exaggerated lithotomy position and the bladder filled, a horse-shoe incision 1.5 cm. anterior to the anus was made, and the rectum separated from the bladder, by blunt dissection. Hemorrhage was slight and easily controlled. An incision into the middle lobe exposed a concretion the size of a hazel-nut, which was shelled out. As part of the concretion had infiltrated the surrounding gland substance, this part together with the tissues was removed. The prostate was here dissected from the urethra without difficulty. As the prostate was incised on both sides of the concretion to effect its removal, but slight hemorrhage occurred. The wound was closed, with gauze drainage. Convalescence was practically unimpeded. The pain and vesical tenesmus had disappeared since the operation, confirming the supposition that the stone was the causative factor of the bladder symptoms. Microscopic examination of the prostatic tissue revealed an increase of the interstitial tissue together with an atrophy of the glandular structure. It was infiltrated with microscopic concrements. Chemical examination of the concrement unfortunately was not made.

NEW YORK OBSTETRICAL SOCIETY.

Stated Meeting, held October 8, 1901.

Dr. H. J. Boldt, in the Chair.

Dr. Egbert H. Grandin presented a specimen of "Tubal Gestation."

Multilocular Cysts of the Kidney.

Dr. G. G. Ward presented this specimen and gave a complete history of the case. Multilocular cyst of the kidney is a rare disease. It is almost always bilateral. Dickinson found only 1 case in 26 in which it was unilateral; Richie, 2 in 88; Lejars, 1 in 62, while Henry Morris found 4 in 7 cases. The average age was 45 years. It was considered hereditary by some authorities, but not by others. Bar reports 3 cases in one family, and Carl Beck found a similar instance. Henry Morris operated upon 5 cases (nephrectomy) and 2 were well seven years and three years after; this would apparently justify nephrectomy in those cases where the other kidney was found to be normal by palpation or inspection through the incision.

Placenta Duplex, or Biloba.

Dr. George L. Brodhead presented this specimen because of its great interest and rarity, and also because of the fact that what may be termed the supplementary placenta measuring from 15x9.5 cm. was of about the same size as the main placenta, which measured 14.5x11 cm., to the center of which the cord was attached. There was a space of about 5 cm. between the two placental masses which were connected by chorion and three fetal vessels, one of which was of large size. The fetus depended as much upon one placenta as upon the other. The one point of clinical importance to be remembered in connection with a specimen of this nature was that the supplementary portion (placenta succenturiata) may remain in the uterus and give rise to trouble; hence, the necessity of a careful inspection of the placenta immediately after its expulsion.

Mammary Changes of Menstruation.

Dr. J. Clifton Edgar presented to the Society an oil reproduction from Nature of the mammary changes produced incident to the menstrual epoch. The painting was not a selected one, but was taken from a number of cases seen during the past ten years in 600 consecutive examinations for evidences of rape. Both in medicolegal cases and in the diagnosis of pregnancy in private practice had he been impressed with the analogy between the changes in the nipple, primary areola, veins and Montgomery's tubercles in the menstruating and pregnant condition, the latter being limited to the first three months. He drew attention to the prominent veins, the darkening and edema of the areola, the erection and congested nipple, and the fact that a slight serous discharge, yellowish in color, caused dry scales to form in the orifices of the milk ducts. His observations lead him to conclude that the condition, especially among the upper classes in nulliparous women, was rather the rule than the exception, and also that very often the mammary changes of the first third of gestation can not be distinguished from those occurring in the premenstrual period of gestation; that, in fact, the mammary changes of early gestation are valueless even for an uncertain diagnosis of pregnancy.

Dr. Charles Jewett had been accustomed to attach some diagnostic importance to the mammary changes in first pregnancies in the absence of pelvic disease, and the fact that mammary changes counterfeiting pregnancy were present at the outset of menstruation did not wholly destroy the value of these signs as evidences of pregnancy. Approaching menstruation, as well as pelvic disease, must be excluded, and the other early signs, nausea and a skipped period, etc., must be considered. The question raised by Dr. Edgar recalled a case seen by him within a week or two. The subject had been exhibited as a pseudo-hermaphrodite. It was rather one of arrested development of the genitals in a male. The penis was very small and there were rudimentary testicles in the scrotum. There was no vagina, no external organs of generation, nor ovaries. The man, who was about six feet tall, was beardless; his breasts were large and as pendulous as those of a woman who had borne children; the areolæ were pigmented. The abdomen was pendulous and was marked with lineæ albicantes, which extended down over the upper portion of the thighs.

Comparative Study of the Immediate Recovery of Patients Following Vaginal and Total Abdominal and Supravaginal Hysterectomies—130 Cases.

Dr. LeRoy Broun read this paper. It has frequently been said that statistics are of little value in determining the worth of any method of operating and, he believed, that there was much reason for such a widespread opinion, since too many factors enter into the make-up of such reports to render them of much service to the operator seeking the best methods. A small percentage of deaths simply shows either the skill of the operator, or an unusual run of fortunate cases, or both. Three years ago he was an ardent advocate of the vaginal route of operating, believing that the after-recovery of the patient was smoother, and knowing that there are but few intra-pelvic growths that can not be removed by this route. During this time and for two years previous, this choice of route was adopted whenever it was possible to do so by Dr. Cleveland and himself at the Woman's Hospital. The results were excellent and apparently left nothing to be desired. During the two years past upon the same service this method had been unconsciously and gradually, to a large extent, replaced by the abdominal route, the object being to exercise as much conservatism as was possible. There were many staunch advocates of both methods of operating, but it was not his object to bring together such arguments but to compare the immediate recovery of patients following the performance of these classes of operations. With this end in view he brought together all the hysterectomies performed during the last two years on two of the services in the Woman's Hospital. These had been arranged under the respective heads of vaginal hysterectomies, complete abdominal hysterectomies, the cervix being removed, and supravaginal hysterectomies, the cervix being left.

Vaginal hysterectomies, 34 in number, were done after the following method: Hemostasis of the uterine arteries was obtained by the vasotribe or angiotribe. After complete separation of the uterus and the diseased adnexa, the broad ligaments were clamped off, one clamp on each side being used. Sterile gauze packing was loosely placed—well above the ends of the clamps—and lightly filling in the intervening space and the vagina. The clamps were removed at the end of twenty-four hours. The gauze packing was all removed by the seventh day, its removal being commenced on the fifth, unless there was some indication to the contrary, such as a rise in temperature, when its removal was commenced earlier.

Complete hysterectomies were 35 in number. The method here pursued was that adopted by the majority of operators. The uterine arteries were ligated with catgut. The ovarian arteries were obliterated in the majority of cases by the Skene electric clamps: when this was not used they were tied off with catgut. The peritoneum was not closed, the raw surfaces being simply covered with sterile gauze, the free end of which protruded from the vagina. This gauze was not disturbed until the fifth day unless there were indications. As in the vaginal hysterectomies it was all removed by the seventh day.

Supravaginal hysterectomies consisted of 54 operations; they were done in the manner customary with the majority of operators. The ovarian and uterine arteries were secured on both sides with catgut. The anterior and posterior flaps were united with running catgut Lembert sutures shutting off the stump of the cervix and leaving no raw surface exposed. The intervening dead space between the flaps was either drained for twenty-four hours by a small portion of gauze protruding the cervical canal into the vagina, or no drainage was used.

The above description of the technique used was given in order the better to compare intelligently the results obtained from this comparative study. A period of ten days from the time of operation was considered ample to determine the exact source of recovery of the patient; within this time any secondary infection that might arise would have usually shown itself. From the tabulated records of each class of operation a composite chart was made, both of the temperature and pulse. No fatal terminations were included in the comparison because it was his desire to determine if there was any difference in the smoothness of the recovery, as evinced by the temperature and pulse record. For the information of any desiring to know the death rate the following was given: 36 vaginal hysterectomies, 2 deaths (1 insanity, 1 sepsis); 36 complete hysterectomies (abdominal), 1 death (1 sepsis); 59 supravaginal hysterectomies, 5 deaths (4 sepsis, 1 pneumonia). A careful study of the composite charts reveals a remarkable similarity in the curve of recovery of both the temperature and pulse in each class of operation. There was shown to be a slight difference in favor of the vaginal route; this operation, however, is practically the same from a surgical standpoint as the complete abdominal hysterectomies with the absence of the abdominal incision and sutures. This slight difference he attributed to the presence of the sutures in the abdominal wall and not to any advantage of operating through the vagina. From the composite temperature and pulse curve there was only one conclusion to be drawn; that from this standpoint it is a matter of choice and individual preference with the surgeon, the patient making as even a normal recovery after one method of operating as from that following another. To further study the recovery after these operations he compared first the vaginal and complete abdominal hysterectomies as belonging to one class of what he called the open method, i. e., drainage through the vagina. Both have gauze drainage, which must be removed; one has, in addition, the abdominal wound, which is to the patient the most prominent feature of the operation. This wound, with its pain and frequent dressings, impairs the morale of the patient. Coming intimately in contact with the patients after these two classes of operations, the difference in their mental equilibrium impressed him strongly. After the gauze drainage was removed in both, the patient following the vaginal hysterectomy is thoroughly at ease, mentally and physically. The one following the abdominal hysterectomy has the wound in the abdomen uppermost in her mind and is anxious for some time. Of the two methods of operating he regarded that by the vagina the more difficult and to obtain the same results as by the abdomen required a larger and wider experience in operating. He referred, of course, to complicated cases of adherent diseased adnexa, and not to the simple removals of cancerous uteri. The abdominal route, with the assistance of a full view of the field of operation by the Trendelenburg position, and a complete isolation and cutting-off of the intestines by gauze pads, was, in his estimation, much the safer method. Here adhesions severed under the eye and injuries to attached intestines can be more intelligently avoided. In performing these two classes of operations it was not their custom to close the pelvic peritoneum in either. The raw surfaces are covered loosely by sterile gauze packing, the free end of which extends into the vagina. It had never been their experience to find the adhesions between the plastic roof formed over the gauze and the intestines to give rise to any trouble, nor was he aware of any being reported by others.

Supravaginal hysterectomies: The above open methods involving as they do a necessary contracting granulating cavity, and attended with foul discharge, while safe, was still at variance with the refinement of surgery, where primary union is sought and the avoidance of open suppurating wounds is expected. The recovery of patients from this class of operation was surgical in every respect; there was no suppurating cavity to close by contraction and granulation. The method had the additional advantages of leaving the cervix which is said to be the seat of sexual feeling in women. The vault of the vagina is also kept intact and its elasticity maintained. He did not regard, however, the operation as materially shortened by leaving the cervix, for in total hysterectomy the extra time consumed in removing the cervix is largely compensated for by the rapidity with which the drain of sterile gauze covering the denuded surface is introduced, this covering consuming less time than the closing of the peritoneal flaps over the cervical stumps. A study of the composite temperature and pulse curves of the 54 cases of supravaginal hysterectomy showed a remarkable similarity in the recovery of patients from this class of operation as compared with the composite charts of those recovering from total abdominal and vaginal hysterectomies. In other words, while the method is more surgical, there is, however, no advantage gained in the ease of recovery so far as the temperature and pulse curve would indicate. Late ligature infection and the danger of septic absorption through the larger area of connective tissue exposed has been frequently urged against vaginal and total abdominal hysterectomies. This was not in accord with the experience at the Woman's Hospital. In those operations where it was considered safe to do so ligatures were replaced by the vasotribe, Skene's electric clamp or the ordinary clamp. When ligatures were used No. 2 size was employed. That there must be some absorption was evident, but in his experience it did not have an appreciable effect upon the temperature or pulse of the patient. A close study of the individual charts in both classes of operations bore out this statement: the open vault of the vagina precludes any retention of the secretions above. The true advantage of the supravaginal method was in the absence of any drain with its attendant painful removal, the absence of resulting suppurating cavity, and the time gained in the discharge of the patient from surgical care. The leaving of the cervix, while of distinct advantage, is accompanied by some risk, since, if secondary infection occurs through its canal the effusion under the flaps now made septic can not be reached except by a secondary operation. The dead space necessarily existing between the peritoneal flaps and the cervical stump had always been to him a source of concern. That the effusion here is usually taken care of by the patient is known to all and is shown by the even temperature curve of the 54 cases reported. That this satisfactory outcome was not always in accord with his personal experience was true. To avoid this secondary infection the habit of closing the cervical stump was customary although not universally adopted. The method of draining into the vagina by a small gauze wick protruding through the canal of the cervical stump, and which was removed at the end of twelve or twenty-four hours, he thought to be a questionable one, since it furnished a channel for infection of the sub-peritoneal space. For the same reason did he regard the leaving of the stump open as cut across liable to permit a secondary infection of the space above. The vagina, even if sterile at the time of operation, can not remain so with the bloody serum escaping over the vulva. The wonder was that when we re-

call Cohn's classical statement that "one germ under proper condition may give rise to more than half a million of similar organisms within twenty-four hours," that with the draining of the cervical stump into the vagina secondary infection under the peritoneal flaps is not the necessary sequence instead of being only the occasional occurrence. When such an infection does occur it is fortunately in most instances of a mild type and the confined pus is liberated by gentle stretching of the cervical stump.

The writer than detailed the cases that terminated fatally already referred to in the beginning of the paper. As a result he drew certain conclusions. It was noted that the percentage of mortality in the 36 cases of vaginal hysterectomy was 5.5, that of the 36 cases of complete hysterectomy was 2.75, while that of the 59 cases of supravaginal hysterectomy was 8.33. When it was recalled that the temperature and pulse record, as shown on the chart, of all cases recovering was practically the same in one class of operations as in the others; when it was further borne in mind that the vaginal and complete hysterectomies were with few exceptions performed on patients with purulent adnexa associated with dense adhesions, and in whom the possibilities of infection from the condition present were greatest, the difference in the mortality became more striking than the percentage death rate showed. The deduction from the data was in direct opposition to Dr. Nobles, who, in his finished article of four years ago on "Hysterectomy for Fibroma" from a collection of 345 cases of supravaginal amputations by five American operators, a death rate of 4.9 per cent. He (Dr. Noble) also quoted Olshausen's table of 806 vaginal hysterectomies with a death rate of 5.6 per cent., as opposed to 520 total hysterectomies with a death rate of 9.6 per cent. He thought that if the different techniques of the various operators were known some reason for this difference might be seen. The question of draining the sub-peritoneal space of supravaginal hysterectomies through a dilated cervix was one in which operators were not yet in thorough accord. The usual method of those who advocate drainage of this space was to insert through the dilated, or longitudinally divided cervical stump a gauze wick which was removed in 24 or 48 hours after the operation. That this drainage through the cervix was a bad practice he was personally convinced. All of the five deaths from supravaginal hysterectomy, with the possible exception of one, were caused by sepsis. Three of these cases could not have been septic from the pathological conditions present. Of the two remaining, one had in addition to the fibromyoma a pyosalpinx which was unruptured and had a retroverted uterus with pyosalpinx. Here there was no rupture in removal; even if ruptured there was every evidence from the history that the pus was sterile. In all the fatal cases the sub-peritoneal space was drained by the gauze wick through the cervix. There was no other conclusion but that through the drainage channel the infection traveled, and this was in keeping with the literature on the subject, chiefly that coming from the Johns Hopkins Hospital. Fortunately, in the large majority of instances in which drainage was carried out no infection occurred. Miller, in his bacteriological study of the cultures made from the interior of the uterus and of the pus from diseased ovaries and tubes, reports, in the Johns Hopkins Bulletin, the following results: In 44 cases of hysterectomy mostly for pelvic inflammatory disease the cultures from the interior of the uterus were all negative. In 51 cases of pyosalpinx, ovarian and pelvic abscess, the cultures were negative in all but one; in this the gonococci were found. During the past six months in all the cases of supravaginal hysterectomies it was the custom in their service to close the cervical stump with catgut sutures before uniting over it the anterior and posterior flaps of the peritoneum. Up to the present there had been no secondary infection.

A review of the various facts brought out in his study led Dr. Brown to the conclusion that: 1. While the finished result of a supravaginal hysterectomy was most satisfactory, the operation was, however, marred by the possibility of a secondary infection, at times terminating fatally. When this infection does occur it can be reached only by secondary operation. 2. The chances of this infection occurring are greater when the sub-peritoneal space is drained through the canal of the cervical stump, or when the canal is left open. There is every reason to close the stump as offering the best results. 3. Total abdominal hysterectomy, though not such a finished operation as the supravaginal, is, however, one in which there is less likelihood of any secondary complications, and though objectionable on account of the suppurating cavity to be closed by contraction and granulation, yet offers to the patient a surer means of uninterrupted recovery. This conclusion, while at variance with Olshausen's large collection of cases in which he gives a 5.6 per cent. death rate for supravaginal, and a 9.6 per cent. for total hysterectomies is, however, the only one to be drawn from the collection brought together.

Therapeutics.

Alcohol and Tobacco Habits.

A subscriber asks whether or not drunkenness and the tobacco habit can be cured at home, and the treatment for the same.

The liquor habit can certainly be better handled in some well regulated, reputable sanitarium for nervous diseases which is conducted and supervised by capable and experienced men.

The success of treatment at home depends a great deal upon the condition of the patient and his ability to exercise self control over either of the habits. If this is impossible then, of course, compulsory measures must be taken. The treatment should consist of alteratives and tonics.

D. R. Brower, in an article on treatment of chronic alcoholism, recommends the following as an alterative:

℞.	Auri et sodii chloridi .....gr. 1/10-1/8		006-0075
	Pulv. resinæ guaiaci .....gr. ii		12

M. Ft. cap. No. i. Sig.: One such to be taken one hour before each meal.

As a tonic the following is recommended:

℞.	Tinct. nucis vom. .....ʒii	8	
	Tinct. capsici .....ʒiii	12	
	Tinct. cinchonæ comp. q. s. ad.....ʒiii	96	

M. Sig.: One dessertspoonful after each meal in water; or:

℞.	Tinct. nucis vom. .....ʒss	16	
	Tinct. capsici .....ʒi	32	
	Ext. lupulini flu. .....ʒiii	96	
	Inf. gent. comp. .....ʒiss	48	

M. Sig.: One dessertspoonful three or four times a day.

Careful attention must be given to elimination by the skin, bowels and kidneys; the diet should be properly regulated. If anemia is present it should be corrected by the administration of iron in some form, and when there is general loss of strength and mental feebleness the following sometimes serves a good purpose:

℞.	Strychninæ sulphatis.....gr. 2/3-i		04-06
	Syr. hypophos. q. s. ad.....ʒiii	96	

M. Sig.: One teaspoonful three or four times a day.

Treatment of Dysentery.

Hughes, in *Med. Record*, recommends the following in the treatment of dysentery:

℞.	Acidi sulphurici dil. .....ʒss	16	
	Tinct. opii deod.		
	Spts. camphoræ, āā .....ʒi	32	
	Tinct. capsici		
	Spts. chloroformi, āā .....ʒss	16	
	Spts. vini gallici .....ʒiss	48	

M. Sig.: One teaspoonful every three hours if necessary; or:

℞.	Magnesii sulphatis .....ʒiss	48	
	Acidi sulph. dil.		
	Tinct. opii deodor., āā .....ʒii	8	
	Aq. chloroformi q. s. ad..... .....ʒiii	96	

M. Sig.: One dessertspoonful every four hours.

Treatment of Zona (Herpes Zoster).

The following formulæ to be employed in the treatment of herpes zoster is recommended by *New York Med. Jour.*:

℞. Acidi tannici
Bismuthi subnit., āā 3ss 2
Zinci oxidi
Amyli, āā .....gr. lxxv 5
M. Sig.: To be applied locally.

Kaposi recommends the following, if powders seem to irritate:

℞. Ceræ flavæ 3iiss 10
Olei olivæ .....℥i 32
Ext. opii (aquosi) .....gr. vi 36
M. Sig.: For local application.

Lestikow employs the following:

℞. Acidi boracici .....gr. xl 2 66
Cocainæ hydrochlor. .....gr. viiss 50
Vaselini 3vi 24
M. Sig.: Apply locally and cover with cotton or gauze.

Treatment of Pertussis.

T. J. Mays, in *Med. Record*, recommends the use of counter-irritants over the region of the pneumogastric in the neck, by applying strips of mustard plaster about two inches wide from the angle of the jaw to the clavicles on each side of the neck, two or three times a day until the effects of the mustard are evident. He states that amelioration of the spasmodic cough is the result. He sometimes uses the following locally instead of applying the mustard:

℞. Chloralis hydratis
Menthol
Pulv. camphoræ, āā .....℥ss 16
M. Sig.: Apply locally several times daily.

Painting the same area with tincture of iodin twice a day, until irritation of the skin is produced, is of benefit. In stubborn cases he injects silver nitrate over the vagi beneath the skin, using three to six minims of a 2/5 per cent. solution of the drug, preceded by an injection of a few drops of cocain solution.

Treatment of Hemorrhoids.

The following combination is recommended by Anderson in *Med. Record*:

℞. Hydrastin
Pulv. aluminis, āā .....gr. xv 1
Cocainæ muriatis .....gr. viiss 50
Ol. theobrom. q. s.
M. Ft. suppos. No. xii. Sig.: Insert one every night.

To Check the Diarrhea in Typhoid Fever.

℞. Acidi carbol.
Ext. opii, āā .....gr. i 06
Bismuthi subnit. .....gr. xviii 1 20
M. Ft. pil. No. vi. Sig.: One pill three times a day.

Method of Applying Hot Fomentations.

Below is given the proper method of applying hot fomentations to different parts of the body. While it may seem a simple thing to do, there are too many physicians who are unable to give specific directions to attendants in carrying out such procedures. The following methods are advised by the *Pacif. Health Jour.* The necessary articles are two or three pieces of flannel each one yard square, a pail of boiling water and a towel. First, get all the articles for treatment in readiness in a convenient place; have the water boiling hot. Then the patient is to be prepared by being put in a position so that the part to be fomented will be easily accessible, protected only by covering that can be readily thrown back. The feet should be kept warm. Next take one of the squares of flannel, or fomentation blankets, and spread out smoothly upon a convenient surface in readiness to receive the wet, hot blanket. Taking another fomentation blanket fold to suit the part to be treated. For instance, if the stomach or abdomen is the part to be treated, fold the blanket double three times, that is, so that it will be one yard long, one eighth yard wide, and eight thicknesses. Holding one end in each hand, dip the center up to within a few inches of each end into the boiling water, twist each end tightly in opposite directions, and pull, thus wringing the blanket until the water will not drip from it. Quickly unfolding the blanket to the required size, lay it upon the dry one in readiness; fold in the ends and fold the dry blanket over it, thus retaining the heat and rendering it bearable to the patient. Place it upon the parts and leave until comfortable, occasionally passing the hand under it to prevent burning. Then renew by using the third blanket for the wet one, allowing no lapse of time between the two fomentations. Repeat the process until the object is obtained, being careful that the patient is not left uncovered at any time during the treatment, as the hot moist surface will become readily chilled if exposed for any length of time.

Treatment of the Throat in Scarlet Fever.

The following is given by the *Med. Standard* as a local application to the throat in scarlet fever:

℞. Acidi carbol. 3ss 2
Glycerini
Aq. camphoræ, āā .....℥i 32
Potassii chloratis .....gr. x 66
Aquæ q. s. ad. .....℥vi 192
M. Sig.: Use as a gargle or spray.

As a local application in the form of a spray or to be applied with a swab, hydrogen peroxid diluted with two or three parts of water is universally recommended.

As an antiseptic and for the itching of the skin the *Standard* recommends the following:

℞. Ichthyol 3v 20
Lani .....℥x 300
Olei olivæ .....℥i 32
M. Sig.: To be applied locally as an inunction.

Treatment of Sore Throat.

As stated in the *Dietetic and Hygienic Gaz.*, one of the best remedies for sore throat is a compress worn over the throat at night. A piece of muslin or light cloth about half the size of an ordinary handkerchief should be folded so as to cover a space of about three or four inches, wrung lightly out of cold water, and placed around the neck. This should be covered by a piece of rubber cloth, oil silk, or oiled muslin. A long, narrow strip of dry cloth should now be wrapped around the neck in such a way as to hold the compress firmly in place. If this compress is so put on as to retain its place, prevent evaporation, and exclude the air, it is an admirable remedy. It should be put on when retiring at night and taken off in the morning on arising, the neck being then washed off in cold water and rubbed until the skin glows.

Medicolegal.

Can Not Bind the State by Promise of Free Treatment.—On the second appeal of State Hospital vs. Fountain, an action against the guardian of an insane patient, the Supreme Court of North Carolina holds that the contention could not be sustained that the ward's estate was not liable for the expense of maintaining and treating her at the hospital because the guardian, upon his qualification as such, applied to the superintendent to know if any charge was made for patients who were able to pay, and was informed that no charge was made for any person, and thereupon his ward was allowed to remain in the hospital. The court says that the contention could not be sustained as it is too well settled that its agents or officers can not bind the state by any contract they may make, when not so authorized to do; especially in violation of the express statute (Section 2278 of the Code of 1883) which allows the admission into the institution of others than indigent insane person upon payment of proper compensation.

Right of Recovery for Operation.—The second appellate division of the Supreme Court of New York has affirmed the judgment of the trial term in the case of MacEvitt vs. Maass, which was reported on page 520 of THE JOURNAL of Feb. 23,

1901. As the appellate division restates the case, the physician who brought this action against a husband to recover for services rendered as physician and surgeon to his wife, after examination of the patient, told the husband that a surgical operation for an internal trouble was necessary, whereupon it was agreed between them that he would perform the operation for $75. The physician testified that a further examination, a few days later, revealed that the first diagnosis was erroneous; that the condition of his patient was more grave than first supposed; that the operation first suggested was not necessary, but that a different and more severe operation was required, which, unlike the former, jeopardized life; and that he told all these things to the husband, who consented to the operation then advised, but that nothing was said between them upon the subject of the fee. Under these circumstances, the court thinks that the question was properly submitted to the jury whether the physician superseded the original agreement based upon the first examination, and it holds that the verdict, which it states was for $275, should not be disturbed. And it is of the opinion that there was evidence sufficient upon which to base the verdict rendered, because there was proof in the record of an operation with the attendance of four physicians and six nurses; an operation severe in character, two and one-half hours in duration, which required the knife, and which was followed by many daily visits, covering a period of between two and three weeks. Then, two experts who attended upon the operation, and one of whom was present at the subsequent visits, were called, and placed a value on the services rendered, and the court holds that the plaintiff was not confined to a hypothetical questioning of such experts, for they were entitled to give their opinions upon what they knew of the services.

Medical Examiner and Statements as to Health.—Section 1812 of the Iowa Code provides that, where a life insurance company's medical examiner or physician acting as such under the rules and regulations of the company reports an applicant to be a fit subject for insurance, the company "shall be thereby estopped from setting up in defense of the action on said policy . . . that the assured was not in the condition of health required by the policy at the time of the issuance or delivery thereof, unless the same was procured through the fraud or deceit of the assured." Now, it is evident, the Supreme Court of Iowa says, in the case of Peterson vs. the Des Moines Life Association, that the medical examiner or physician contemplated in this section is the person who examines the applicant, and determines his condition of health, and reports whether he is a proper risk. It is no doubt customary for life insurance companies to have a general medical advisor or director at the home office, whose advice is taken into account in determining whether the risk shall be accepted; but the person who makes the actual examination, and reports on the applicant's condition, is evidently contemplated by the statute as the medical examiner or physician referred to. Then, it says that it is to be noticed that the estoppel declared by the statute is as to the condition of the health of the assured at the time the policy was issued. There may, no doubt, be warranties as to other matters not relating to the health of the assured—such as his place of residence or occupation—breach of which will avoid the policy notwithstanding the statute; but, so far as the statements relied on as warranties relate to the health of the assured and his acceptability as a risk on that account, the company is estopped from showing their falsity, unless they constitute fraud or deceit in procuring the report or certificate of the medical examiner. Nor does the court agree with the contention advanced that the estoppel applies only to the condition of health of the assured at the time the policy is issued, and that statements as to previous disease, treatment by physician, accidents, etc., are warranties any breach of which will avoid the policy. In other words, it thinks that the estoppel relates to all matters inquired about so far as they bear on the health and physical condition of the applicant as affecting the risk, whether they refer to the time the policy is issued or to some previous time; for the ultimate question is whether the applicant is a suitable person to accept as subject of life insurance. Moreover, it says that the tendency of the courts, without the aid of legislation, has been to construe statements as to previous accidents and diseases into mere assertions on the part of the applicant as to what he knows of his personal knowledge, or may be presumed in good faith to know, instead of strict warranties regardless of personal knowledge.

Current Medical Literature.

AMERICAN.

1. **Transmission of Tuberculosis.**—Repp reviews the questions of the transmission of tuberculosis by meat and milk to animals, both experimentally and by natural methods, giving abstracts from the literature, and also the question of the similar transmission to man. There is no experimental evidence whatever of the transmission of tuberculosis to man by tuberculous meat, and its transmission by natural methods in this way is only presumptive. Of course, meats, if thoroughly cooked, destroy all the danger. As regards milk the evidences, though comparatively few, give presumption that it is possible.

2. **Prostatic Hypertrophy.**—Whalen's article gives the symptoms, diagnosis, and treatment of enlarged prostate. He thinks that dilatation with steel sounds or dilators has a certain value, but it has never given complete relief. Operations for drainage are only palliative measures. Where permanent drainage is to be established, he prefers it by perineal urethrotomy rather than suprapubic drainage. Galvanopuncture, iodin injections, and ligation of the internal iliac are obsolete methods as is also castration. He does not favor vasectomy as recommended by Harrison. Perineal section and enucleation as done by Nichol and Alexander are of value in selected cases if the removal is complete, but operations which do not attack the hypertrophy of the lateral lobes are not radical and can not effect a permanent cure. Suprapubic section or prostatectomy is the most curative procedure and if there is a suspicion of stone or tumor, it will always be found most satisfactory. The operation advised by Belfield, of combined suprapubic and perineal section, is often done, but personally he has never had any difficulty in removing the hypertrophied prostate by simple suprapubic section. Where it is difficult, a great help will be found by placing a finger of one hand in the rectum and exerting counter-pressure while enucleation with the other forefinger is being done. Lack of thoroughness and care in selecting cases is responsible for the difference of opinion regarding prostatectomy. The mortality, he thinks, is largely due to the advanced stage of the disease and the poor systemic condition of the patient. The Bottini operation, he believes, is palliative in most cases. He thinks that this and prostatectomy are the only procedures to be tried at the present time. The larger the prostate, the more favorable for prostatectomy, while for the smaller ones the Bottini operation is indicated. Prostatectomy should not be done as a last resort; the time to do it is before great damage has been done to the bladder and kidneys. If this plan is followed and spinal anesthesia used in place of the usual anesthetics he thinks that the mortality of prostatectomy can be brought as low as, if not lower than, the Bottini operation and that the results will be far better.

4.—See abstract in THE JOURNAL, xxxvi, p. 1726.

9. **Splenic Anemia.**—The continuation of Wentworth's article in this issue is largely a review of the literature.

10. **Ambroise Pare.**—The conclusion of the memoir of Ambroise Paré by Cumston is here given, with notes on some of his contemporaries. It forms an interesting historical study and the author has evidently devoted considerable research to the subject.

11. **Tubercular Peritonitis.**—In this concluding portion of Fontaine's article the treatment is discussed and the various theories as to the effect of abdominal section are noticed, but the author does not, himself, express a preferential judgment. The percentage of recoveries in the surgical cases is evidently not too encouraging—from 25 to 35 per cent. The percentage

of mortality increases the longer the cases are observed. It is evident that the surgical treatment of tubercular peritonitis is far from being settled. In fibrous, caseous or ulcerative cases surgery reports only bad results and has no effect except as a palliative for bowel constriction or grave complications. In cases of ascites and encystment both medical and surgical methods have strong claims, and only long and more frequent observation of the results will decide for which the balance lies. The author thinks that in complicated cases it is better to give the medical treatment a thorough trial because there is already a tendency to spontaneous recovery and medical measures may suffice. The results from the medical treatment seem to be about as good as from the surgical treatment, and the latter will be as efficacious a little later on, if found necessary. The medical treatment advised seems to be to keep the alimentary canal aseptic, to prevent local irritation, to use proper diet, ice-bags, and in acute cases, for the first few days, to treat like an acute peritonitis. After that, no opium, but hot fomentations for the pain, if necessary. Keep the diet fluid, use calomel and salines in divided doses, intestinal antiseptics, tonics and such general remedies as are supposed to be curative for tuberculous affections. The treatment should continue for several months under careful observation. In no case should we forget to add the tonic influence of fresh air, which has so much benefit in this as in other forms of tuberculosis.

13.—See abstract in The Journal, xxxvi, p. 1582.

15. **Biopsy.**—The name biopsy is given by Besnier to a sort of autopsy on the living, consisting in excision of eruptive lesions or fragments of tumor for the purpose of histologic examination. The advantages of it are in furnishing a means of diagnosis, and the disadvantages are slight. The patient can usually be brought to consent. The operation done under asepsis avoids infection and the time required for the removal of the part and the pain are exceedingly slight. The preferable instrument is the sharp Graefe knife, which cuts out the flap pinched up, including the desired piece. Hemorrhage is usually insignificant. Local anesthesia may be generally dispensed with and cocain injections are undesirable on account of the edema they produce. The incised tissue should be at once immersed in the fixing agent that has been chosen. Biopsy is indicated whenever the practitioner is face to face with a cutaneous lesion, or an accessible lesion of the mucous membrane, where definite diagnosis can not be otherwise made. In tumors and ulcerations of doubtful character tending to infect surrounding tissue the indication is absolute and pressing, though in other cases diagnosis may not be so imperative. The greatest use of the method is for the clearing up of epithelioma-appearing cases, etc. These are often difficult to distinguished from tuberculous ulcer, gummata, actinomycosis, lupus, and various other conditions. Cutaneous tuberculosis also furnishes frequent occasion for fruitful resort to biopsy, and syphilis and leprosy must also be taken into account, also mycosis fungoides, and sarcoma. Biopsy is optional in benign malignant tumors, which are troublesome on account of their number and persistency. In special cases Darier has resorted to biopsy for the diagnosis of certain common dermatoses, which in atypical forms present problems in diagnosis. He says to sum up: "Biopsy is an operation which furnishes an easy and rapid means for establishing or confirming a diagnosis otherwise impossible or doubtful in the case of various dermatoses and cutaneous tumors. It is too often neglected by some, and very rarely employed by others. For this reason he has believed it worth while to recall it to the attention not only of dermatologists but of physicians and surgeons generally.

17.—See abstract in The Journal of July 13, p. 138.

20. **Resistance Exercise.**—The use of resisted movements of the part of the body in which the definite resistance is to be governed, with the object of strengthening the muscles which cause the movements, is by Little referred to under this head. He says that they are useful in various deformities of the foot and hand and describes the methods, especially an automatic arrangement. To make the child, especially the young ones, who are difficult to get to apply themselves to these exercises, he has devised an arrangement whereby the proper movements can be affected by ringing of a bell, and very few children can resist this temptation. In order that they should not tire of the exercise it is essential that they should not be allowed to play with the machine too long. Its use should be reserved for stated periods and be made rather a treat than a task. In an intelligent child of 10 years or more this is hardly required, but in many cases it is better to substitute the resistance of a small weight to that of the nurse's hand on account of any possible carelessness on her part.

21. **The Lane Lectures.**—Morris defines syphilis as an exanthematous fever diluted by time, and discusses its cutaneous manifestations, the polymorphous character of the lesions, hereditary syphilis, modes of inoculation, diagnosis and treatment. He favors the early use of mercury before the constitution has become infected and this continued with occasional intermissions for two or even three years. The worst of the aggravating agencies is alcohol, and tobacco still further aggravates the condition. He suggests as a prevention a sort of social ostracism; if the contamination of a healthy person through the carelessness of a diseased one who knows himself to be such could be made a criminal offense, it would be still better. The prevention of syphilis has become a matter of urgency in Europe, as according to Fournier, it is more serious than it was of former years. The public should be wakened to the importance of a systematic effort to stamp it out. Leprosy is also considered, and its prodromal period, which may extend over years, the evolution of the disease and other manifestations, its geographic distribution, its relation to colonization and undoubted contagion are discussed. He gives some remarks also in regard to medieval leprosy and points out that the segregation of lepers is a necessity to stamp out the disease.

26.—See abstract in The Journal of October 5, p. 930.

27. **Transmission of Yellow Fever.**—The mosquito theory of the transmission of yellow fever is endorsed by Doty, who finds that while it is not yet demonstrated that there may not be other means, it is really evident that the disease is not contracted by personal contagion or through the medium of clothing, bedding, cargoes and vessels. He thinks we are justified in changing the quarantine regulations to conform with the latest views.

29. **Cinchonism and Hearing.**—Seiler finds from experiments with a complete set of test tuning forks and occasionally a musically trained subject, that the ordinary tinnitus aurium due to middle-ear disease never transgressed the limits of pitch from d-1 (297 vibrations as the lowest point) to f-2 (704 vibrations as the highest), and that these subjective noises had no effect on the vocalization or articulation, but that they would invariably affect the sounds which had the same or nearly the same number of vibrations per second. The subjective noises of so-called cinchonism, as produced by the various drugs such as quinin, sodium salicylate, etc., he found to be invariably of a very high pitch, varying from as low as the g-3 (1584 vibrations) to as high as the i-4 (3960 vibrations) and often even higher. In the few cases of musically educated persons whom he has examined and who were familiar with the aural analysis of sound, inquiry elicited the fact that the noise was composite in character, being made up of a variable number of individual sounds. These were sometimes harmoniously blended to form a chord, the fundamental tone of which was always constant in pitch, but varied with the drug producing the noise—usually the lowest with quinin, and the highest when sodium salicylate produced the subjective aural sensation. The third fact which he observed was that any composite noise of high pitch, such as is produced by the hissing or escaping of steam or the noise of rapidly revolving grindstones, not only interfered with the pronunciation of those consonants, which, according to the investigation of Helmholtz and others, have for their characteristics a combination of sounds of very high pitch, th, s, sh, and z, and the

like consonant sounds of articular speech, but also caused them to be most easily obliterated and consequently most difficult to be appreciated and recognized by the ear. This fact, which is quite familiar to steam engineers and grinders, is to be explained by the well-known acoustic law of interference. The acoustic or physical laws fail us completely when a subjective, in reality physically non-existing noise, such as that of cinchonism, materially interferes, as it undoubtedly does, with the pronunciation of those consonants of high-pitched composite characteristic sounds and even alters the quality and timber of the high-pitched vowel sounds. He does not offer any explanation or hypothesis of what is to him an inexplicable but undoubtedly existing influence of purely subjective and non-externally produced sensations upon a purely physical phenomenon such as vocalization and articulation.

32. **Gouty and Obese Respiratory Conditions.**—The abnormal respiratory conditions in sufferers from obesity have not, Anders says, been studied as much as they deserve. Their pathogenesis is not clear, but the mechanical embarrassment from the deposition of fat throughout the body will largely account for them. He has found the respiratory capacity by actual measurement to be less than 2.5 inches in obese subjects, and it is obvious that such interference with lung expansion must excite dyspnea upon muscular exercise, or over-distension of the stomach and even during recumbency. Dyspnea is more marked in the anemic than the plethoric variety, in which latter type there appears to be compensatory hypertrophic changes in the muscular structure. One thoracic symptom belonging to over-fatness especially mentioned, is pain in the subscapular and intrascapular muscles, which may be acute on moving the organs or attempting to maintain an erect position. The restrictions of thoracic excursions in the respiration and the enfeebled heart action combine to cause passive venous congestion of the bronchial mucosa. Thus we have in obesity a hyperemic bronchitis with troublesome cough and sometimes copious mucoid expectoration, aggravated by weather changes, irritants, etc. The physical signs are variable. Closely connected with this is asthma, which is usually regarded as of cardiac origin, but is favored by respiratory activity. There is also an asthma in obese cases due to gastric disturbance. The active stage is also an accompaniment of obesity and there are reasons to think that both these are dependent upon liver inadequacy. Personal experience leads Anders to think that severe paroxysmal dyspnea seen in obesity is in many cases not a true asthma; it is relieved by assuming and maintaining the erect posture for a short period. When asthma does occur, however, as well as with these cystic dyspneas, the effect of the usual treatment to reduce body weight is liable to aggravate the asthmatic symptoms. His own conclusions as to the question of the relation of the asthma to polysarcia are: 1, that asthma occurs in about 5 per cent. of the cases of obesity; 2, that it only occurs in extreme polysarcia; 3, that there is present a gouty state or history in most cases in which true asthma is secondary to obesity; 4, that about 50 per cent. or one-half of the cases are curable by overcoming the causative condition. He also mentions the bronchial affections in their relation with gout and the association of gout with over-fatness. Asthma may be caused by gout independently of obesity and the usual treatment of such cases is by the antipodagral remedies. There are cases where lithemia rather than gout exists, as shown by high urinary acidity, diminished renal inadequacy, etc.

33. **Nephorrhaphy.**—The title of this article is rather misleading, as only the first part of it refers to the use of adhesive straps instead of sutures for closing a nephrorrhaphy wound. The larger portion of the article refers to the recognition of misplaced kidney and the operative measures required for its relief. Goelet gives the symptoms which indicate prolapsed kidney, such as chronic congestive disturbance, nervousness, fatigue, palpitation, epigastric pain, dragging pain in the loin, inability to rest on the left side, bladder irritability, jaundice, pain simulating appendicitis, ovarian trouble, renal colic, etc.

34. **Multiple Malignant Neoplasms.**—Warthin describes a case with autopsy where there were sercoma, carcinoma, and myomata co-existing. Coley's serum was ineffective and he finds that it produced simple necrosis in parts where it was injected, and suggests that if spontaneous necrosis and degeneracy so frequent in malignant tumors is to be regarded as one of the factors in the production of tumor cachexia, excessive necrosis produced by injections of toxins must be favorable to the rapid development of cachexia, with also the dangerous systemic effects of the substances injected.

40. **Dysentery.**—Monroe considers that dysentery is often produced by exposure and that straining at the stool may often induce sufficient irritation to cause it. He thinks also that dysentery is contagious and he noticed that it seemed to be communicated in one case by a bed which had been used by a former sufferer and in others by the use of houses which had been closed for months after dysentery had occurred in them. Therefore, he thinks, in the epidemic form it will be well to isolate patients, thoroughly ventilate houses, frequently changing the bed and clothing and disinfecting discharges and other exposed articles. In epidemics he has found it good to begin with calomel, then followed with quinin and subnitrate of bismuth when the discharges change. In some epidemics he has given tincture of opium and castor oil mixed every four hours after using calomel. He does not see any benefit from astringent injections. He disbelieves entirely in the serum treatments, or rather says he thinks all have more or less of a humbug in them and credits any effects to carbolic acid which is combined with them all.

41. **Malaria.**—Favill insists on the diagnosis of malaria being confirmed before specific treatment is commenced and he has long since come to withhold his prescription of quinin until he has made a microscopic diagnosis. If we go ahead and give quinin and the case is troublesome or dubious the evidence of infection that we are trying to establish may be destroyed, though it may be there all the time. Quinin is not of diagnostic value in a multiplicity of cases. In this part of the country we should see but few cases of estivo-autumnal fever and they are most likely to give trouble. It is hard to say always what is the best to do with a case of estivo-autumnal fever; it runs such a course, baffling and irregular, so as to be almost beyond our therapeutic reach. When we have decided to give quinin, the question is how much? It is a grave question whether we should treat the case hypodermically or not. The reason quinin does not act when given by the mouth is because it is not absorbed by the intestinal canal. He asks: What alternative administrations have we? Three, hypodermic, rectal and intravenous. The rectal method is unsatisfactory, but he has seen cases where he did not dare to resort to the hypodermic administration and the rectal method had to be relied upon. The hypodermic administration of quinin is possible and extremely effective, but there are objections to it, especially the dangers of local necrosis, and the condition of the patient favors this sometimes. The difficult question to settle is how much good quinin will do in certain cases, between the final results and the infection. Have we here a disease infection or have we its indirect result? Unfortunately, in most cases the diagnosis in this respect can not be made and we give quinin because we have nothing else to do. The rejuvenation of the blood becomes an important question in the terminal aspect and here comes in the use of judgment and experience in therapeutics. Finally, the best way to administer quinin in simple cases where there is a distinct paroxysm, is before the onset of the paroxysm, or during it, but we have few of these cases now. For the most part the drug can be given throughout the day and will almost invariably fulfill its purpose. The drug must be administered according to the necessities and possibilities of each case; the point is to get it into the blood in sufficient quantities. This leads to the statement that there is no such thing as a dose of quinin. The dose of quinin is what will produce the desired effect, whether it be 3 or 30 grains and this will depend on the conditions of the case.

51. **School Text-Books on Physiology.**—In the opinion of Scott, a good common-school text-book should first have its

teachings such as are sustained by the most recent scientific investigations. 2. It should represent sufficient anatomy. 3. It should give due emphasis to the cellular microscopic structure of the tissues so that the cell activity of the organs can be comprehended. 4. The physiologic anatomy of the body should be so explained as to be within the comprehension of the pupils. 5. The physiologic processes should be so emphasized that they will stand out as distinct. 6. Sufficient emphasis should be placed upon hygienic matter, which, however, should not be distributed through the book, but given after the other parts. He goes over the text-books that have been offered and points out their defects and merits as they appear to him. Martin's "Human Body" is too illogical in its order and arrangement, but the later revisions are better than the former ones. The best book of all which he speaks of is Thornton's "Physiology," which is more nearly ideal than any he knows of, though he speaks well of Colton's and Blaisdell's physiologies also.

52. **Hemorrhoids.**—The operation mentioned by Mason for the cure of internal hemorrhoids consists in first preparing the patients with cathartics and enemas and restricted diet and then inserting a pledget of cotton saturated in a 10 per cent. solution of cocain, up the anus about two inches. After about five minutes the piles will be partly free from sensation. Then have them forced out by the patient, if possible, if not, by other means, and grasp the tumor lightly at the base with the notched clamp and inject it full with a 2 per cent. solution of cocain. After about a minute a clamp is closed as tightly as possible and all the piles above the notched edge cut off. With a curved needle threaded with catgut, stitches are passed through each notch and tied tightly and after all are tied the clamps are removed and a neatly closed wound that heals by primary union is the result.

60.—This article has appeared elsewhere. See abstract in THE JOURNAL of October 19, ¶18, p. 1067.

67.—See abstract in THE JOURNAL, xxxvi, p. 1650.

69.—See abstract in THE JOURNAL, xxxvi, p. 1653.

70. **Cesarean Section.**—A case of Cesarean section is first reported by DeLee and the relative propriety of the different operations in cases of dystocia discussed. He argues for the propriety of craniotomy in certain cases, holding that the mother is more important notwithstanding the teachings of the Catholic church. While the mortality from Cesarean section is comparatively low, it still is sufficient to make the operation a serious one, while that of craniotomy may be said to be absolutely *nil* at the present time. We must consider that fact that a large proportion of children die in early life, which would affect the value of the child's life as compared with that of the mother. There is also the possibility of the child being a monstrosity, idiot or imbecile and he asks what we would do if the child were illegitimate or if the patient was a dwarf, imbecile or criminal. Would it be desirable to perpetuate or multiply such cases? The physician, he thinks, is legally and morally obliged to obtain permission, however, to perform any operation and in case of division of opinion, the mother desiring a child, and the father desiring, if possible, to save the life of the mother, he thinks the husband's word should be the governing one. In any case the fact should be thoroughly laid before the parties concerned and if permission for Cesarean section is not granted the following courses are open: 1. Expectancy. Not infrequently the calculations of the obstetrician have been entirely upset by nature and a child spontaneously born. 2. Prophylactic version. 3. High forceps. When these fail craniotomy steps into its right. No man should wait until the patient is in actual danger or use forcible means to save himself by reason of the morbid sentimentalism against having destroyed a child. If the child is still-born or dies in a few days he has destroyed it in the worst possible manner as far as both mother and child are concerned. In advanced cases the mortality of Cesarean section is much higher than when performed early and may be out of the question. When the patient has been in labor more than twenty-four hours, when she is presumably infected, when operation has been attempted by unskilled hands, Cesarean section and symphysiotomy should be prohibited. The child should be sacrificed and premature labor induced, or the former operations under ideal conditions may be then performed.

75. **Toxicity of Urine in Pregnancy.**—In this article Stewart reports experiments which seem to indicate that all the fresh urine which killed mice must have contained microorganisms at the time of injection and in every case septicemia or the presence of bacilli could be demonstrated in the blood. Urine passed by the patient over boric acid usually contains a convulsive poison which is deadly in 100 per cent. of cases, and when the urine is drawn by catheter under strict surgical asepsis the mortality is greatly reduced, and when the urine is so drawn and immediately boiled the mortality is still further lessened.

76. **Prolonged Pregnancy.**—In the case here reported by Taussig, the woman had three pregnancies while under observation, two of normal length and one in which without question the duration of gestation lasted 323 days. She was able each time to fix the date of last menstruation. The child died in each case shortly after birth so that there was no question of amenorrhea from lactation. He reviews the published cases of prolonged pregnancies and says that we have here a mass of evidence which should make the most conservative acknowledge that this condition occurs in the human race and it has long since been proven to occur in lower animals.

79.—This article has appeared elsewhere. See THE JOURNAL of October 5, ¶45, p. 941.

87. **Varicocele.**—Bradley recommends the suprapubic operation for varicocele, that is to say, tying the veins near the inguinal canal. He finds by correspondence with military surgeons that the method has been in use by Major Banister, who describes it as one of the most successful surgical procedures, without risk to life and well adapted to military service, and by Major Borden, who believes that varicocele should never be considered a cause for discharge, but operated upon in this manner. Bradley's method of performing the operation is locating the cord first by palpation and making an incision directly over the external ring, 1 to 1½ inches long. After reaching the sheath of the cord and opening it, enlarged veins frequently present, which can be picked up, drawn out and excised. They are separated by blunt dissection and ligated one-half to three-fourths inch above the testicle by two catgut ligatures. The veins thus ligated off are excised and the stumps drawn together by ligatures left long enough for this purpose. After tying, the approximation is made more perfect by threading the ends of the ligatures and taking a few continuous sutures. The cord is now replaced in the sheath which is closed by fine catgut continuous sutures; the deeper tissues are approximated by continuous catgut and the skin by subcuticular silkwormgut. A sterile cotton collodion dressing is applied and a suspensory bandage. In a week the dressing is removed, the silkworm sutures taken out and a suspensory worn for some time thereafter.

99.—See abstract in THE JOURNAL, xxxvi, p. 1414.

100. **Celloidin Capsules.**—McCrae has studied the agglutination phenomenon by the method of enclosing the bacilli in capsules inserted into the abdominal cavity of animals, and in this article he gives the description of making these capsules. He fits the body of an ordinary drug capsule over the end of a tube which is constricted a little above its end. The tube is heated and then the capsule melts on the tube. Then both are plunged into a thin liquid celloidin so that it adheres directly to the capsule and the glass and this is repeated until the desired thickness of celloidin is obtained. The gelatin is then melted out by filling the capsule with water and placing in a test tube half filled with water and then heated in an autoclave. Into a capsule thus prepared a culture is inserted, care being taken not to wet the glass of the tube which is well fused with a blow-pipe flame, thus making a sterilized capsule. 1. He found that the capsules thus made allowed dialysis when placed into the peritoneal cavity. 2. The normal tissues, un-

stimulated, do not possess the power of causing agglutination; they do not require to be stimulated by the presence of the bacterial bodies, but will produce their share of the agglutinins when acted upon by the bacillary products. 3. Agglutination follows the insertion, in the peritoneal cavity, of "capsulated" bacilli; it gradually increases in degree, and on the removal of the capsule, containing the bacilli, begins to disappear. 4. Varieties of bacilli, related closely in morphology and cultural reactions, do not, as a rule, produce serums which inter-agglutinate.

101. **Hypodermic Injections.**—Meltzer has tried experiments with multiple injections as compared with single ones in the rabbit and he finds that the former, though the total amount of substance injected is less, are more effective. Thus the distribution of a certain quantity of poison among several places of the body is more effective than the injection of the same quantity in a single dose into one place.

102. **Cyclic Albuminuria.**—The authors report a case of cyclic albuminuria in an otherwise apparently healthy young man in which they noticed the excretion of proteid from hour to hour under various conditions and point out the independence of changes in the diet or medicine. No relationship between the volume of urine eliminated and the quantity of proteid excreted has been ascertained, but the albuminuria was checked while the patient was in a horizontal position. Mendel and Hooker say the attempt to refer this to attendant circulatory changes in the kidneys is, for the present, no more than an interesting speculation.

110.—This article has appeared elsewhere. See THE JOURNAL, xxxvi, ¶23, p. 843.

111. **Chloroform-Oxygen Anesthesia.**—Wohlgemuth's article describes his method of employing oxygen combined with chloroform with the view of avoiding asphyxia and describes his apparatus. The details of the latter are too elaborate to be given here. His experience with this form of narcosis comprises, so far, more than 300 cases, which he thinks is sufficient to authorize him to bring his experience before the profession. He has never seen any signs of suffocation, and patients who bore ordinary anesthesia badly stood this method splendidly. In twelve instances the weak irregular pulse improved during narcosis. 166 patients were fully conscious immediately after operation; 13 required between 8 and 30 minutes, and 1 slept three hours; 21 dispensary patients got off the table and walked home. Kidney irritation was never observed and he thinks with this method an overdose of chloroform is impossible. He hopes that future trials will establish the value of the method.

113.—See also title 79.

115.—This article has appeared elsewhere. See THE JOURNAL of October 19, ¶62, p. 1066.

121. **Symblepharon.**—In the case reported Marple has employed the Thiersch grafts with success in a case of symblepharon. The method is not new, since Hotz used it in 1893, and others a little later. He describes his technique and remarks that the grafts should be from one-third to one-half larger than the surface to be covered, as allowance should be made for subsequent shrinkage. Whether to introdnce the grafts the same day the symblepharon is divided will depend upon the amount of bleeding; if slight, there is no objection to proceeding at once. It is best to use a shell of transparent glass to protect the cornea. If there is much pain and infiltration the shell must be removed. In dividing the symblepharon it is important to obtain a pouch of normal depth so that the lids are easily closed over the shell after it is introduced. In the case presented the operation was done with success two years ago and the results seem to be permanent. He does not wish to be understood as advocating the use of Thiersch's grafts in all cases of symplepharon. In many cases we can get along without them, but in several of his own cases he is sure that no other method would have succeeded nearly so well. The grafts are taken by him from the inner surface of the arm.

124. **Quackery.**—The dangers and temptations of quackery are noticed by Fronczak, who offers the following suggestions for its prevention: In the first place medical schools should admit only young men whose antecedents, surroundings and personal character are such as will not admit of any probability that they will afterwards dishonor them by quack methods. The son of a patent-medicine man will possibly follow some such a course as the father, and the employe of a cure-all medicine office will surely use the quack tactics of his former employer. 2. The medical student ought to be an educated man to a high degree, a liberal man, though one that will not tolerate anything outside the confines of honesty of judgment, common sense and morals. After graduation from a course of at least four years he should have hospital experience of one or two years. A thorough knowledge of medical science thoroughly equips the physician and at the same time prevents him from diverging to the side-track of dishonesty or quackery. 3. The medical students should be taught all the simple means of healing and nursing. They should be forewarned against imposters and attempt to protect the community by exposing quack methods. 4. They should try to popularize as much as possible writings on hygiene and simple medical preventatives. 5. Physicians should never antagonize one another or speak ill of one another or use unethical or improper means of securing practice. In using such they lower the standard of the profession both with themselves and the public and open the field for quacks. 6. State restrictions to practice of medicine should be such as to insure competent physicians and every transgression of the law should be severely punished. The contents or ingredients of all patent medicines should be printed on every bottle or vial and all conspicuous and nauseating advertisements should be prohibited. 7. The medical press of the country should give due notice of all quacks in their neighborhood and the method employed by these and provide physicians with valid and strong arguments to be used against quacks on every occasion. They or the medical societies should see that the newly settled quack should not be allowed to linger. Finally, physicians should be careful in giving their opinion on all new drugs that have not been thoroughly tested or tried. It gives the quack the excuse to say that the medical men do not really know what is good, but condemn one day what they praise another, and try things on their patients dangerous to life and health.

125. **Major Obstetric Operations.**—The conclusions to which Reynolds has been led are as follows: "1. When the conditions are such that the child can be delivered with anything like reasonable ease by forceps or version, one of these operations is preferable to any cutting operation. 2. When the mechanical relations would render forceps or version unusually difficult, forcible and prolonged, and when the mother is in the favorable class, the equally low maternal mortality and the far lower fetal mortality of the Cesarean section renders it the operation of choice. 3. When the mechanical conditions make the intrapelvic delivery of an intact child at term impossible or unduly difficult, the great superiority of Cesarean section over the induction of premature labor in fetal mortality and its extremely low maternal mortality render it again the preferable operation. 4. When the ordinary operations fail and the woman is in the unfavorable class, symphysiotomy is the operation of choice and may be expected to lead to a favorable result for both mother and child in the great majority of cases, provided always that the degree of mechanical difficulty permits of its application. 5. When in the unfavorable class of cases, the degree of relative disproportion between head and pelvis is too great to admit of a safe symphysiotomy, craniotomy to the living child should be unhesitatingly chosen, since the maternal mortality of either form of section is so enormous, and because I can not doubt that the life of the potential mother of many children is of more value than that of any one unborn fetus." He thinks that if these principles are true there are but few if any cases of uncomplicated mechanical obstruction in which a happy outcome is not within the power of prompt and intelligent medical care if applied early. He insists on the value of pelvimetry and thinks that

any one having a first case of labor in a patient should calculate all the possible contingencies of mechanical obstruction.

126. **Hysteria.**—Hysteria is not confined to the human species, and Ullman reports several cases from the literature, of it occurring in dogs and other animals. In the human species it does not belong to any time, nor is it peculiar to any race. There are certain etiologic factors which if allowed to play will cause definite symptoms of this disease to appear in any race. The influence of emotions such as traumatism, general disease, such as typhoid, etc., and the influence of sexual organs, and intoxication. The Israelites appear to be more especially subject to this condition, and he explains the fact by their heredity and antecedents. In the black race he believes that it occurs in their native state, and in spite of the observation of Hammond to the contrary, the most typical cases of hysteria were very common during the slave period as May has shown. Correspondence with those who have had much experience with the colored race inclines him to believe that the negro is as subject to hysteria as the white with the same intelligence, education and environment. The Indian aborigines of this country were liable to be hysterical, though less so probably than some others. A few individual cases of the trouble have been noted in connection with their religious superstition, but as the Indian becomes more and more civilized he becomes more subject to it. He does not find much evidence of its frequency among the Chinese. He does not believe it is as frequent with them as in the white race. It is a condition common to all people, but it affects certain races more than others, such as the Jewish and Latin peoples. This is due to environment rather than to hereditary antecedent qualities.

132. **Injection Treatment for Hernia.**—A case is here reported of hernia involving principally the omentum with a very small knuckle of the intestine which was reduced en masse, but again came down and called for operation. A large number of adhesions and extensive agglutination was found, which required careful dissection and made the operation tedious and apparently doubtful in its outcome, though the patient ultimately recovered without a bad symptom. The existence of these complications was attributed to the injection treatment which had been instituted about one year before.

140.—See abstract in The Journal of September 28, p. 850.

143. **Ocular Paralysis.**—In cases of ocular paralysis in the very early stages when there is still a chance for treatment to be effective the diagnosis is sometimes difficult. The limitation of motion is often not demonstrable at all, hence the primary deflection not observable, and secondary deviation not satisfactorily shown. Weymann offers the following three rules; "1. Diplopia appears in the field of action of the paretic muscle. 2. The advancing image belongs to the paretic eye. 3. Paresis of any obliquus or external rectus produces homonymous; any other muscle heteronymous diplopia." Using stained lenses of equal density of tint, but differing color, for both eyes, best fusion colors, shows the binocular single picture in fusion tints, while the changing color of the parting images facilitates prompt recognition. Examples are given showing the application of these rules.

146. **New Formed Physiologic Macula.**—Bordley reports a case where after operation for squint an excentric portion of the retina took up and performed perfectly the functions of the macula, with not only the same acuity of vision as the normal one, but was also capable when stimulated of assisting in the most perfect associated ocular movements.

156. **Esophagotomy.**—The case reported is one in which a child had swallowed a metal clasp and the operation for its removal is here described. Taylor reviews the literature of esophagotomy for such cases and insists on the importance of the Roentgen rays, and the value of their expert interpretation. He believes it is always advisable to attempt to suture the esophagus with catgut, because then if we do not close the wound at first we can diminish its extent. The external wound should be packed with gauze, there being no objection to using one or two sutures at each end to diminish its length. The dressing should be changed very frequently. Boric acid is the strongest antiseptic which should be used about the wound for fear of doing damage. From a review of the literature he feels sure that the question of short and fat neck should not be a special factor in determining our selection of method of reaching the foreign body. We should be guided only by its position as located by the skiagraph.

157. **Drug Habits.**—According to Pettey there are four points in the successful management of these cases: 1. Thorough elimination; 2, support of the vital functions; 3, relief of suffering; 4, entire control of the patient and his surroundings. He believes in the use of hyoscin to relieve the suffering of these cases of morphin habitués. It does not affect the vital functions or leave after-effects and the patient should be kept under its influence for twenty-four hours from the time abstinence symptoms begin to make their appearance. If the beginning course has been thoroughly carried out it will be hardly found necessary to continue the administration of hyoscin more than twenty-four to thirty-six hours and at the end of this time the patient will remain free from pain and nervousness, will sleep from five to eight hours, have no craving for the morphin, and in a few days have an appetite that is hard to satisfy. In most cases no after-treatment is necessary. He does not believe in alcohol or strychnin. Other stimulants should be interdicted. During the period of treatment which under the rapid withdrawal method lasts but a short time the patient should be separated from his family and for ten days to two weeks afterwards to avoid sympathy and over-attention. which have a bad effect.

164. **Sigmoidopexy.**—The operation recommended by Mott is that of McLeod, published in the *Lancet* of July 19, 1890, and described, though not commended, in Treves' "Manual of Surgery." The operation is performed by first making a laparotomy, a 2-inch incision, a little internal to the anterior iliac spine, dividing the muscle layers according to their fibers, opening the peritoneal cavity and reaching with the index finger for the bougie introduced per anum and held by an assistant. This is quickly found, crooked up by the finger and fixed by two stout catgut sutures to the inner side of the wound in the abdominal wall. The suture pierces the peritoneal and muscular coats, but, of course, leaves the mucous lining intact. Close the peritoneum with a catgut suture and the transversalis and internal oblique with silkwormgut. The external oblique was joined by a strong catgut and the skin incision closed by interrupted horsehair sutures. In his case the progress was uneventful, and he thinks, instead of this being an extreme measure as characterized by Treves, it is much simpler and more rapid of performance and causes less shock and loss of blood than complete excision and incurs no more risk than any other ordinary laparotomy operation.

British Medical Journal, October 19.

A Discussion on Renal Tension and Its Treatment by Surgical Means. Reginald Harrison.—Dr. Harrison calls attention to the evidences that the kidney may be in a congested state and in a condition of extreme tension, causing the cortical tissue to be enormously swollen and changed to a deep coffee color in extreme cases. He compared the condition to that of the eye in glaucoma and suggests the term renal glaucoma as not an inappropriate one. A somewhat similar condition might also exist in the testicle, which results sometimes in sterility. Four illustrative cases are reported and discussed and the surgical method of relief described. In incising the capsule of the kidney for relieving tension he prefers doing so along the convex border, while punctures may be made almost anywhere where the engorgement seems greatest, but he thinks it is well to avoid the pelvis. Drainage is an essential part of the process and may be continued some days or even weeks. As to the question as to which organ should be selected, he thinks there is not much choice unless there is something to indicate it, such as the presence of pain. Both organs are usually involved in an inflammatory condition, though possibly not to the

same degree. In double nephritis, however, relief of tension in the one kidney relieves the other. In the discussion following, Dr. Cousins remarked on the favorable results of the operation for these conditions, and said the most favorable cases for surgery appear to be those associated with acute nephritis and infection through the blood. Tension may be caused by partial or complete retention of urine, from infection or from chronic alcoholism.

Certain Points in the Operative Treatment of Renal Calculus. J. HUTCHINSON.—The importance of the Roentgen rays in the operative treatment of renal calculus is particularly emphasized by Hutchinson, who sums up as follows: "1. The *x*-rays (except perhaps in stout subjects, or in the case of very small stones) enable an exact diagnosis as to size, position, and number of renal calculi to be made. 2. They enable the surgeon in performing the operation of nephrolithotomy to do so with the least possible injury to the kidney, and to dispense with bringing that organ on to the surface of the wound. 3. Limited incisions made directly over the calculi through the renal pelvis are to be preferred when practicable. Such wounds of the pelvis heal well. 4. Before the operation it is most important to get the urine into a healthy condition. The administration of urotropin before and afterwards is of much value. 5. Renal calculi, however small, should be operated on as soon as they are positively diagnosed. Their danger to the kidney structure and to the patient's life bears no relation to their size."

Radical Cure of Femoral Hernia. R. H. PARRY.—Parry remarks on the objections to the usual methods of radical operation of closing femoral hernia from below, claiming that efficient support can not be provided for the approximation of structure outside of Poupart's ligament, that the femoral vein is in danger of being injured or compressed and that a depression is left above the crural ring. The method which he proposes consists in exposing the crural ring from above and attaching the conjoint tendon to Cooper's ligament, thus effectually blocking the entrance by structure which can be readily displaced to do this and also be adjusted so as to avoid pressure on the veins. The technique consists first in a curved incision with the convexity downward from a point a little external to the pubic spine to the middle of Poupart's ligament, raising a flap of skin, ligating and dividing the superficial epigastric vessels and exposing the ligaments. The femoral sheath is opened near Poupart's ligament and the sac and adherent fat now turned out as far as possible with the finger. This avoids the saphenous vein. The sac is then opened and the adherent omentum sutured or ligated and removed. When the fat has been removed on the outside surface the sac is usually much smaller than in inguinal hernia, and the rules for the latter can not always be followed in femoral hernia. If its walls are thin and torn it should be removed and the opening into the peritoneum carefully closed. An incision is made through the aponeurosis of the external oblique immediately above and parallel to the inner half of Poupart's ligament. The inguinal canal is opened and its contents drawn aside to define the lower margin of the conjoint tendon. The transversalis fascia is next divided where it passes beneath Poupart's ligament to form the anterior layer of the femoral sheath. The peritoneum is left intact except where necessary to ligate and remove omentum, which can not be returned through the ring. Retracting the parts at this stage affords an excellent view of the upper surface of the ring, the femoral vein and Cooper's ligament. A catgut suture is passed through the fundus of the sac where it is tied and then through the neck close to the parietal peritoneum and finally carried through the transversalis fascia and conjoint tendon. When the suture is tightened the sac doubles up and disappears beneath the abdominal wall; the suture is then knotted. For attachment of conjoint tendon to Cooper's ligament, a strong catgut suture is carried by a sharp curved needle on a handle through the conjoint tendon and transversalis fascia at a point opposite to the outer margin of Gimbernat's ligament, passed horizontally beneath the muscle and fascia for about one-half inch and then brought through them. The inner end of the suture is now passed through Gimbernat's ligament, the outer through Cooper's ligament, and both are brought out in the groin. The second suture is applied in the same way, but while the outer end is being passed through Cooper's ligament close to the femoral vein care must be exercised lest the accessory obturator artery be punctured. Traction on the end of the sutures brings down the conjoint tendon and transversalis fascia over the crural ring, and after it has been determined that no undue pressure is made on the vein the sutures are tied. Two or three medium catgut sutures connect the conjoint tendon with Poupart's ligament to assist in keeping down the tendon, and to strengthen the inguinal canal. The rest of the operation is completed in the usual way, two or three silkwormgut stitches keeping the edges of the skin together, while approximation of the rest of the wound is secured by a continuous horsehair stitch. No drainage of any kind is used. The same procedure has been adopted in strangulated hernia. The sac is opened and the bowel carefully examined. If found in a fit state and the condition of the patient suitable, operation as detailed is performed.

Prevention of Shock During Prolonged Operations. W. H. BROWN.—The method suggested by the author for the prevention of shock consists in having, as soon as the patient is under ether, a competent surgeon open a selected vein and begin to transfuse as the major operation proceeds, the amount injected being governed by the state of the pulse and the loss of blood consequent on the operation. In his cases he has used as a rule about five pints of fluid. The advantages of the method are that everything is at hand and prepared for. There is no emergency operation of transfusion in cases of extreme shock. Everything is prepared for beforehand. He thinks many times such a method would enable one to bring to successful issue cases which would otherwise succumb to the extra shock of operation.

The Lancet, October 19.

The Treatment of Hemiplegia. LEONARD G. GUTHRIE.—The following is the summary of Guthrie's article as regards the treatment of hemiplegia: "1. Neglect and want of treatment aggravate severe, and retard the recovery of mild, cases. 2. The evils to be foreseen and guarded against are articular adhesions, late rigidity, and muscular atrophy. 3. Articular adhesions should be prevented by passive movements of each joint from the very first. 4. Faulty positions of the limbs should be constantly corrected or they will become chronic. 5. Contraction of muscles should be treated by endeavors to improve the nutrition of their weaker opponents. 6. Massage, passive movements, and to a less extent, electricity, should be used with this object. These agents not only counteract muscular atrophy from disuse, but probably take the place of normal stimuli and invigorate the neurons. 7. The recovery of mild cases may be often hastened by re-education of movements. Want of re-education frequently prevents recovery. 8. Re-education consists in a combination of passive and active exercises. 9. Movements should be first encouraged in those parts which naturally tend to recover first. 10. Incoördination and general weakness of limbs which have yet regained power of movement should be treated by exercises and mechanical therapeutics. 11. It is important to find out what the patient can do and to make him do it."

Journal of Laryngology, Rhinology and Otology, October.

The Principles of Treatment of Tuberculous Laryngitis. ST. CLAIR THOMSON.—The principles to bear in mind in tuberculous laryngitis according to Thomson are as follows: "1. Pathology and clinical experience show that in the majority of cases the focus of infection is near or in the cricoarytenoid joint. 2. Many cases only present themselves at a stage when the possibility of effecting a cure by local measures is quite untenable. 3. The principle of *primum non nocere* should be constantly kept before us, as many measures which have been tried in this affection have only distressed the patient and hastened the disease. 4. In the light of present knowledge and therapeutic resources, the most rational principle is to attempt to make an early diagnosis of the disease while in an in-

cipient stage. Any persistent or suspicious laryngeal catarrh should be treated seriously on even a presumptive diagnosis. 5. Once diagnosed, the patient should be treated on the principles laid down in the modern method of sanatorium treatment. 6. Symptomatic treatment should be directed to an irritative, catarrhal, or obstructive condition of the air-passages. 7. In addition, silence should be enjoined, the disuse of the voice being proportionate to the degree in which the focus of infiltration approaches or interferes with the arytenoid joint. 8. In cases where the situation or extent of disease do not warrant an expectation of complete arrest of process, treatment should be symptomatic, and in many cases the sanatorium treatment is uncalled for."

Presse Medicale (Paris), September 28.

Lecithin in Tuberculosis. H. Claude and A. Zaky.—Guinea-pigs inoculated with tuberculosis and then treated with lecithin, survived much longer than the control animals. The general health was much improved and resistance to the infection evidently augmented. Similar results were observed in twenty-one clinical cases. The lecithin rapidly modifies the nutritional processes; the amount of phosphorus that is eliminated is very much decreased, while there is a constant tendency to progressive increase of the co-efficient of the utilization of nitrogen. In the early stages of tuberculosis the effect of the lecithin was marked in the remarkable increase in the appetite and weight and improvement in the general health. "The absolute harmlessness and the undoubted benefit to be derived from lecithin render it a very valuable adjuvant in the treatment of tuberculosis." Six pills of 5 cg. each were the average daily dose.

Ko-Sam as a Specific for Dysentery. Cognacq.—Ko-sam is a Chinese drug, which has a remarkable local action on dysentery by reflex vaso-constriction. It has both hemostatic and cholagogue properties, and in Cognacq's experience with twenty-five cases of acute dysentery, proved an actual specific. It is the seed of a shrub which grows in Petchili and is agreeable to take, with no after-effects except occasionally slight, transient gastric disturbance.

October 9.

Orthostatic Albuminuria a Relic of Infectious Disease. C. Aubertin.—Orthostatic albuminuria is not a distinct morbid entity, but is merely a variety of albuminuria dependent on certain conditions in the circulation, but always on the foundation of some more or less characteristic renal lesion. In five cases observed by Aubertin, it first appeared during convalescence from scarlet fever, and was accompanied by symptoms indicating an acute nephritis. Reviewing the cases that have been published, Aubertin notices that some preceding infectious disease is mentioned in nearly every case, and is not excluded in the others. In his cases the albuminuria was purely orthostatic, that is, it occurred after standing, without fatigue. It was uninfluenced by the diet, or muscular exercise when the patient was reclining.

Revue Medicale du Canada (Montreal), October 16.

Anilin in Treatment of Tuberculosis.—The thesis of Eva Abramovitch (Montpellier) proclaims the efficacy of pure anilin by inhalation as a disinfectant of the lungs. She first discovered its therapeutic properties by the error of a druggist, who gave her a bottle of crude anilin when she applied for a balsam. She relates that she was yellow, green and blue in turn, but at the end of three weeks her cough was entirely cured. After numerous tests and experiences, she announces that redistilled, pure anilin is perfectly harmless, and is absolutely destructive to Koch's bacillus. Inhaled into the lungs it induces active hyperleucocytosis; the character of the sputa in pulmonary tuberculosis rapidly changes and all expectoration finally ceases, while the patients rapidly gain in weight. There is no danger from its use for the heart, nervous system nor kidneys, when they are intact, and even in pathologic conditions or when an over-dose has been taken, the disturbances are transient. She recommends for inhalation a 25 per cent. solution of freshly redistilled anilin in a saturated solution of boric acid to which a little menthol has been added, gradually increasing the proportion of the anilin. The inhalations should be repeated twenty-five to thirty times every half-hour, and the treatment kept up long after all stethoscopic signs have vanished, in order to prevent recurrence. The anilin can also be applied in inunctions or may be administered by the mouth.

Formalin Test for Albumin in the Urine. Tretrop.—The physician can carry with him a small vial of formalin as it is not a corrosive, and can test the urine at the bedside. Four or five cubic centimeters of fresh urine are heated in a test tube nearly to boiling point, and a few drops of 40 per cent. formalin are added after it is removed from the flame. If there is any albumin in the urine it coagulates like the white of an egg, and accumulates on the surface of the urine and also settles on the walls of the tube. After pouring off the fluid, the proportion of albumin can be determined by weighing or by the size of the coagulum left.

Semaine Medicale (Paris), October 9.

Associated Epidemics. V. Babes.—Epidemics of certain complications of diseases are sometimes observed in hospitals. The ordinary pyogenic micro-organisms seem to acquire unusual virulence from some reason, and attack inmates of hospitals debilitated by their previous affection. Babes has described several extensive epidemics of this kind. In the present communication he reports an epidemic of forty cases occurring in two rag-pickers' communities, which presented the clinical picture of exanthematous typhoid fever. But neither during life nor at the autopsy was it possible to discover any typhoid bacilli nor typhoid lesions, although the serum reaction was pronounced in most cases. The influenza bacillus was found numerous in the eight cases that came to autopsy. The disease could not have been an aborted typhoid fever, as the agglutinating reaction in several was absent at first and became positive only later. Neither could it have been simple grippe, as the grippe bacillus was not always found at first, but appeared later, and it was found in old lesions, pneumonic, softening or gangrenous foci. The evidence seemed to indicate that in this epidemic there was some hidden factor, some primary infection of which it was impossible to detect the causal agent, and that the influenza and possibly also the typhoid bacillus were secondary arrivals, and that the latter for some reason was unable to thrive and produce its usual lesions. Possibly there may have been no specific primary infection but merely a peculiar lack of resisting power on the part of the poorly-fed subjects due to their unhygienic environment, close to the city dumping grounds in clay-pits. This lack of resistance on the part of the organism may have allowed the ordinary microbes, streptococci and others, to prepare the soil for the invasion of the influenza or typhoid bacilli. In any event, study of this epidemic at Bucharest last winter proves that the discovery of the influenza bacillus does not necessarily indicate an epidemic of grippe, nor do the positive results of the agglutinating test demonstrate that typhoid fever is epidemic. Both of these elements of diagnosis may be found in the evolution of a special syndrome—an associated epidemic—which yet is neither la grippe nor yet typhoid fever. It also proves that every epidemic is not inevitably produced by a single specific microbe, but that certain associated epidemic diseases may occur, induced by ordinary causes on a predisposed soil, by associated factors, or by specific germs grafted on other equally specific infectious diseases, undetermined as yet. In the associated epidemic described, the primary affection probably differed in different patients. In the majority the fundamental disease seemed to be typhoid fever, but in two of the patients it seemed to have been measles, in another, general infection by the pneumococcus, streptococcus and staphylococcus, and in another, arteriosclerosis evidently aggravated by the invasion of the grippe bacilli which were found numerous in every case.

Berliner Klin. Wochenschrift, September 30.

Splashing in the Stomach a Sign of Atony. B. Stiller.—Pure atony of the stomach is not necessarily accompanied by

muscular insufficiency. The motor function of the stomach is twofold, a concentric contraction and the peristalsis for evacuating its contents. Atony is defective concentric contraction, and muscular insufficiency is defective peristalsis. The former may exist alone, but it predisposes to the latter, and the expelling power may vary with the time, the length and the quality of the meal and even with the mood. But at any time during digestion the splashing sound can be elicited, revealing the underlying atony. It is usually merely one manifestation of a congenital atony of the entire organism, entailing enteroptosis, nervous dyspepsia and general neurasthenia. Stiller suggests the term congenital universal asthenia as descriptive of this specific and extraordinarily frequent condition. The first and most constant sign is the splashing sound in the stomach, which reveals the atony of the organ, and when supplemented by the changes in resonance in different positions, renders further investigation with the sound superfluous.

Apparent and Actual Disease Foci. BUTTERSACK.—The incubation, localization and other features of infectious diseases are best explained, Buttersack thinks, by the assumption that the germs first find their way into some lymph gland or glands. They may remain latent in these foci for days or years, but when they finally surmount these barriers, the lymph channels afford an easy means of conveyance by which they invade the entire organism and settle at the points for which they have a special predilection or which are the least effectively protected by the resisting forces of the organism.

Treatment of Continuous Flow of Gastric Juice. L. V. ALDOR.—In the five cases of gastrosuccorrhea which Aldor describes, the symptoms—pains in the stomach, excessive thirst, obstinate constipation and frequent vomiting—were so severe that malignant disease was suspected. The condition was finally differentiated by the large amounts of gastric juice found in the stomach at all times, the low specific gravity of the stomach contents, the large proportion of uncombined hydrochloric acid and the defective digestion of starch, with the positive exclusion of motor insufficiency of the stomach. The subjective symptoms frequently subsided but the objective persisted unchanged. Only one case is known in which this excessive secretion of gastric juice was unaccompanied by any symptoms. Belladonna has a strong inhibiting action on the secretion of gastric juice, and atropin is the only drug at our disposal with which gastrosuccorrhea can be influenced. It should be supplemented by an alkaline saline water taken before and after every meal, as hot as the patient can bear. By this means the gastric juice is neutralized and a sedative action obtained, while the results are equivalent to a rinsing out of the stomach. One or two teaspoonfuls of Carlsbad salts taken during the day are also useful. Lavage of the stomach will seldom be found necessary with this treatment. Even when the symptoms are most severe, a single lavage in the morning will be found sufficient. Starchy foods should be avoided. The systematic and abundant ingestion of fats not only supplies the required calories in a non-nitrogenized form, but modifies the secretion of gastric juice.

Centralblatt f. Bakteriologie (Jena), September 10.

Insects as a Living Culture Medium for Germs of Contagious Diseases of Man and Animals and for Experimental Research. C. VON HOLUB.—For two years Holub, of Odessa, has been experimenting with insects, inoculating them with ulcus molle, syphilis, etc., or infecting them by feeding them on substances contaminated with the fluids from soft chancre. In every instance he found that the entire body of the insect offered a pure culture of the specific microbe. He did not have a single failure in 1000 experiments. The insects were of numerous varieties, orthoptera, rhynchota, hemiptera, coleoptera, lipidoptera and diptera, from grasshoppers and bugs of numerous kinds to beetles, butterflies and flies. Most of his tests were with ulcus molle, and although other bacteria were sometimes present in the fluid inoculated, only pure cultures of the typical streptobacillus developed, and its virulence was enhanced. The infected insects lived twenty-one days as the maximum, if fed, and only fourteen days if not fed. The development of the microbe was evident in twelve hours. The inoculations were made with a fine needle in the heart or throat. An infected insect invariably infected in turn its sound mate, although great care was always taken to make the inoculations as far as possible from the genitalia and digestive organs. Flies fed on the exudate from a case of soft chancre soon swarmed with the specific bacillus in pure cultures. One infected insect always transmitted the infection to others in the same jar. Although ulcus molle is an external disease in man it developed internally in the insects without apparent external manifestations.

Centralblatt f. Chirurgie (Leipsic), October 5.

Heteroplastic Operation for Congenital Dislocation of Hip Joint. O. WITZEL.—The object of the operation described was to supply a support for the head of the femur, as the existing socket was too shallow to hold it. A row of gold-plated nails was driven into the bone just above the acetabulum, forming a strong barricade by the close juxtaposition of the rounded heads of the nails set in a semicircle. The child of 4 first operated on, had a left dislocation with congenital shallowness of the socket. A plaster cast was applied to the entire limb, including the foot, during narcosis, with vigorous extension. After several days of assurance that the cast fitted well and was comfortable, a window was cut in it over the hip joint, and the exposed skin was scrubbed and painted with iodin. A large sterilized sheet was then spread over the child, a slit cut in it over the hip, and the edges of the slit fastened to the skin with forceps just inside the edges of the opening in the cast. The soft parts were then incised down to the fascia, the incision carried 8 cm. on a straight line slanting across the upper portion of the great trochanter. The soft parts were then drawn up out of the way, and after preliminary location of the head, etc., by needle puncture, five or six nails were driven into the bone in a semicircle around the head, forming a fence to keep it in place, the rounded heads of the nails corresponding to the neck. As the pelvic walls are unusually thick in congenital dislocations of this kind, the nails were driven in for 2 cm., the outside ones slightly slanting to prevent any injury to the sciatic nerve. They were 3 mm. in diameter, about 4 cm. long and the points were nearly blunt. A short, thick stick with a depression in the lower end to fit over the head of the nail, was used between the hammer and the nail to prevent injury to the soft parts. The cutaneous incision was sutured with fine silver wire; it lies considerably below the semicircular fence of nails. The effect of this procedure does not seem to differ from that of any ordinary bloodless, manipulative reduction. The nails fully answer their purpose and will in time probably aid in the formation of a bony limbus.

October 12.

Cause of Phlegmons After Amputation of Fingers. C. LAUENSTEIN.—The tendons are usually pulled out in amputating and when the stumps retract, they carry back with them, far into their sheath, the germs of infection. In time a phlegmon develops, which could have been avoided by amputating the tendons without making traction on them.

Centralblatt f. d. Grenzgeb. d. Med. u. Chir. (Jena), October 2.

Tuberculosis of the Bladder. K. R. VON HOFMANN.—This was formerly considered a rare affection, but Hofmann has been able to collect ninety-four communications on the subject that have been published since 1895. Men are more frequently affected, and in adults there is usually a primary focus elsewhere, generally in the kidneys or genitalia. In children, tuberculosis of the bladder is generally primary. Gonorrhea seems to induce a predisposition on the part of the bladder equivalent to trauma. The lesions are mostly small and cluster around the ureteral orifices, but a few cases of general ulceration are on record. Perforation has occurred into the rectum, and one fatal case has been reported in which the bladder perforated into a persisting urachus. In adults, the symptoms are, as a rule, an immoderately frequent desire to urinate, pain, pyuria and hematuria, but in children, the first, principal, and sometimes the only, symptom is incontinence of urine,

with or without pyuria. Instances have been known in which a primary tuberculous cystitis had developed and progressed in a child without causing any symptoms referable to the bladder. The urine is always acid at first, but as the disease progresses and mixed infection is superposed, it gives an alkaline reaction. A tuberculous process anywhere in the urogenital tract favors secondary infection, and the symptoms induced by the latter first attract attention to the primary process. The hematuria usually is slight and appears with the last few drops of urine. Immoderately frequent micturition is soon accompanied by pain, or existing pain may become aggravated. Suspicion of tuberculosis is usually a contraindication to cystoscopy, and the diagnosis must be based on bacteriological examination which is rendered difficult by the resemblance between the tubercle and smegma bacilli. Hesse's culture medium, originally designed for the sputum, differentiates the bacilli better perhaps than any other means. This is a combination of 5 parts Heyden's "Naehrstoff"—a soluble albumin, in its properties midway between coagulated albumin and somatose—5 parts sodium chlorid; 30 parts of glycerin, 10 of agar; 5 of a 28.6 per cent. solution of sodium, and 1000 of distilled water. The smegma bacillus will not grow on this medium. Remissions are sometimes noted in the course of tuberculosis of the bladder, and the affection may have a protracted course of fifteen to twenty years. Complete recovery is not so unusual as is generally assumed, especially in case of primary affection. Treatment is the same as for tuberculosis in general. Goldberg and Richter report cases which remarkably improved under internal administration of ten to seventy drops of a mixture of equal parts of ichthyol and distilled water three times a day in increasing doses. In one case a patient took twenty-five to seventy drops for months without disturbing the digestive apparatus, and with remarkable improvement of the bladder and kidney tuberculosis. Botswood, Chetwood and others recommend nuclein and report satisfactory results. In one case, a tubercular affection of the bladder which had lasted eighteen months, was treated by subcutaneous injections of nuclein for two months and then a 5 per cent. solution was administered by the mouth, with complete recovery of the patient. Bazy and others recommend what they call "the permanent dressing" for the bladder, i. e., injections of 20 to 30 c.c. of a 5 per cent. emulsion of iodoform in fluid vaselin. It is injected into the empty bladder and as soon as the vaselin appears in the urine during micturition further urination is suspended for the time. By this means the emulsion can be kept in the bladder for several days. Janin adds 5 per cent. guaiacol to the mixture. Ramond has reported excellent results from distention of the bladder with air, and Battle with water, but their successes have not been confirmed by others to date. Several writers announce recoveries after cauterizing or curetting the bladder, especially in women. Camero reports 5 permanently cured, 5 temporarily improved and 4 failures out of 14 cases thus treated by curetting; Guyon 8, very much improved and 1 failure in 9 cases. The former calls attention to the necessity of treating the urethra at the same time. The French regard operative interference as merely palliative, but others have secured excellent results with it. Sectio alta is preferable, even for women. Sectio mediana may exceptionally render service as in a case reported by Greiffenhagen in which a caseous perineal abscess had perforated into the urethra, with simultaneous tuberculosis of the bladder, testicles and urethra. Five weeks' drainage of the bladder through the wound in the perineum, followed by the use of the permanent catheter for four weeks, cured the patient, and the cure had persisted a year to the date of publication.—*Deutsche Ztft. f. Chir.*, 1896.

Muenchener Med. Wochenschrift, September 10.

Simplified Intubation. A. RAHN.—No special skill or experience is required for intubation with the tube as modified by Rahn. The family doctor can insert and remove it without the least difficulty or danger. The shape is altered to allow the portion opposite the thyroid cartilage to be smaller in diameter than the rest, while the tube at the lower end is more olive-shaped, and at the upper end flares more like a funnel, the edge sloping downward from the back. Not far from the top a metal hook projects inside the tube about half across its diameter. The tube is inserted by an instrument similar to Krause's "universal loop," with a metal sheath over the wire loop which by a screw can be made to project as far as may be desired. The loop is hitched over the hook in the top of the tube and screwed fast to it. The tube can thus be inserted in the throat as if solidly fastened to a long handle. The child should lie on the bed. One assistant holds the head and gag, another the hands folded on the breast and the feet. The physician holds down the tongue with the left forefinger, and with it also pushes the epiglottis aside. The tube is then inserted with ease. It can be taken out with equal facility, the wire loop catches on the hook, and is then screwed fast to the tube. If strings are used two or three knots should be tied in them close to the tube so that they can be more readily found.

Wiener Klin. Wochenschrift, October 10.

The Spinal Cord in Children and Syringomyelia. J. ZAPPERT.—Schultze has described hemorrhages in the posterior horns discovered in the spinal cords of two infants after difficult delivery. Pfeiffer has also reported a similar case and Zappert now reports another. Schultze's swinging had not been applied in two of these cases, and consequently can not be incriminated in the production of the hemorrhages. It is more than probable that these hemorrhages resulting from traction during delivery, may entail such injury on the surrounding cells that they may prove the foundation on which syringomyelia develops later. But this can not be a frequent cause of the affection, as only four instances are known and Zappert discovered these hemorrhages only once in his research on 200 spinal cords from embryos and infants newly born and up to two years of age. He urges others to inquire if delivery had been especially difficult in the cases of syringomyelia that come under observation. He found many anomalies in the size and shape of the central canal, but does not consider them pathologic in most cases, especially what he calls simple hydromyelia, i. e., an enlargement of the central canal to the rear, tapering into a point and forcing the gray commissure before it into the posterior septum. There is always the possibility, however, that this simple hydromyelia may develop later into cavities, and possibly be accompanied by proliferation of the neuroglia. He was able to discover an advanced phase of this combination in the spinal cord of a 19-months' rachitic infant who had died from bronchitis. The central canal was abnormally large and surrounded by proliferated glia, indicating that the child in time might have had syringomyelia. In the case of one anencephalous infant who died soon after delivery at term, the central canal was enormously large and double in some parts—an evidently pathologic congenital hydromyelia. It was the only spinal cord of the entire number investigated in which the enlargement of the central canal was, as in syringomyelia, most pronounced in the region of the neck. No positive evidences were found in any case of congenital proliferation of neuroglia.

Defective Development of the Kidneys in Congenital Lues. A. STOERK.—Microscopic study of the finer structure of the kidneys during the last months of fetal existence or the first months of life, showed constant vegetative disturbances, pathologic defective development, under the influence of the hereditary deleterious influence. The disturbances were invariably of the same nature in the twenty cases examined and were never found in the sixty control kidneys examined except in two in which inherited syphilis was not absolutely to be excluded.

Alteration in the Pancreas in Case of Diabetes. A. WEICHSELBAUM.—The atrophy invariably noted in the writer's experience in cases of "pancreas diabetes," involved the parenchyma and essentially the cells of Langerhans. If this finding is confirmed by others, it sustains the assumption that these "islands" are vascular glands and that they produce the substance which prevents the retention of sugar in the blood. The unusual abundance of the centro-acinar cells possibly indicates increased function of the organ, a secondary phenomenon en-

tailed by the diabetes. The numbers of granules of fat in the epithelium is possibly also merely a secondary phenomenon resulting from the increased metabolism in diabetes. The age of the eighteen diabetics in whom the pancreas was examined almost immediately after death, ranged from 14 to 75, and the diabetes had lasted from three weeks to nineteen years. All had died in coma. In the only case in which the pancreas failed to show marked macroscopic and microscopic atrophy of the parenchyma, a large glioma was found in the cerebrum. In one case the pancreas was completely indurated and inflammation had evidently preceded the induration. Investigation of the pancreas in cases of other affections showed marked atrophy of the parenchyma, but the centro-acinar cells of Langerhans were spared. Weichselbaum, therefore, is inclined to consider the atrophy of these islands, the characteristic token of diabetes.

Metastatic Ophthalmia in Epidemic Cerebrospinal Meningitis. WINTERSTEINER.—The autopsy disclosed a suppurative pericarditis, an abscess in the thyroid cartilage, numerous subcutaneous hemorrhages and a sacral decubitus. The staphylococcus was found in the pus from the pericardium, but Weichselbaum's intracellular meningitis micrococcus was discovered pure in the suppurative ophthalmia. The optic nerve was sterile.

Friedlaender's Bacillus in a Cerebral Abscess. M. SACHS. Sachs reports the second case on record in which pure cultures of Friedlaender's pneumonia bacillus were derived from an abscess in the brain. In both cases there was coexisting suppuration of the middle ear, which was probably the primary process.

Zeitschrift f. Hyg. u. Infectionskr. (Leipsic), xxxviii, 1.

Penetration of Bacteria into the Lungs. O. NENNINGER.—The experimental research described shows that dust and droplets containing bacteria penetrate to the terminal ramifications of the air passages. Droplets seem to have a greater penetrating force than dry dust. As the lung is in constant communication with the exterior it is not always sterile, but can be found so under favorable conditions. The lung is not a good shelter for microbes and they rapidly disappear from it. No trace of the anthrax bacilli introduced, for instance, in some of the experiments, could be discovered in the lung twelve hours later. The same mechanism which separates and expels droplets in expiration, separates and causes them to be inhaled during inspiration and carried to the remotest air passages. The constant movements of the muscles engaged in speaking, chewing, swallowing and breathing also aid in detaching droplets from the fluids in the mouth and throat. Nenninger compares the germs thus derived to a spark glimmering in the ashes. A conflagration may result at any moment and infection may suddenly flare up in the lung from aspiration of the germs casually finding their way into the mouth, throat and upper air passages.

Zeitschrift f. Orthop. Chir. (Stuttgart), Ix, 3.

Report from Hoeftman's Clinic. STRUBE.—In advanced cases of scoliosis Hoeftman supplements continuous extension on a sloping plane, by Weir Mitchell's method of feeding. The general health rapidly improves in most cases and the patient is then ready for active gymnastic treatment. Among the points emphasized in this profusely illustrated communication are the advantages to be derived from massage in cases of irreducible hernia with adhesions, even of many years' duration. The hernia is taken in both hands and gently pulled outward, with rotating movements. An assistant at the same time pushes the intestines away from the spot inside, with his palm applied to the abdomen below. By this traction in both directions, the adhesions are gradually loosened, and after a few repetitions of the massage, the hernia is easily reduced.

Treatment of Curvature of the Spine. W. Schulthess.—An apparatus on the principle of a standing swing is proving very successful in Schulthess' Orthopedic Institute at Zurich. The trunk is fastened in extension, the arms raised, with spring pads working on the projecting shoulder or back, while the patient stands in a swing which moves on an axis on a level with the deformity to be corrected. An adjustable heavy weight on a long bar at right angles to the swing, travels with it. Schulthess calls this apparatus the "hip pendulum and shoulder pulling and pushing apparatus."

Progressive, Multiple, Ossifying Myositis. W. RAGER.—Microdactylia was noted in 24 of the 54 cases of this affection that have been published. No treatment has any effect, and death finally occurs from the interference with respiration and mastication, but long survival is possible, as the disease runs a very erratic course. It always commences in childhood. In the new case described, the child was apparently healthy except for the deformity in thumbs and big toes. Between the age of 1 and 2 some transient bony tumors were noticed in the forehead. Two years later another appeared in the neck, until gradually most of the voluntary muscles contained these bony tumors, completely suspending their function. The process is first an asymmetrical, local, doughy, edematous tumor, increasing in size for a few days, with pain and sometimes slight fever. The tumor then subsides somewhat, but gradually becomes harder and harder. The lesions became more numerous in this case at puberty. The internal organs seemed to be intact. The parents and other children were healthy.

Iatrike Proodos (Syra, Greece), May-June.

Malarial Psychic Troubles. J. KARDAMATIS.—The nervous disturbances observed in the course of malarial infection are caused by the toxins secreted rather than by the malarial parasite itself. They are usually most pronounced in persons of a neuropathic tendency, and the infection may arouse a morbid predisposition or a latent local or general affection, or it may aggravate an existing disease. The delirium is similar to that of other infectious diseases and the malarial drunkenness like that of alcohol, with the four degrees of agitation, anesthesia, coma and paralysis. Malarial delirium may be subacute, acute or superacute and even acute mania has been observed, but is rare. In the delirium the patient is in a dream from the irritation of the centers of special sensibility, and the delirium is induced by the hallucinations. Psychic troubles are rare in the course of chronic paludism, while those which have been published as first appearing long after recovery from the malarial infection, are dubious from more than one point of view.

Gazzetta Degli Ospedali (Milan), September 29.

Chronic Peritonitis. R. SUPINO.—The aim in treatment of subacute and chronic peritonitis should be to increase the resisting powers of the organism by dietetic and hygienic measures, supplemented by small doses of iron and arsenic. Supino thinks that operation is unnecessary, as spontaneous recoveries occur without it. He combats the ascites by the local application of tincture of iodin. In case of a scrofulous, lymphatic tendency, he has been very successful with daily subcutaneous injections of the iodo-iodid solution recommended by Durante. His experience at the Pisa "Ospizio Marino" has included numbers of cases of "actual resurrections" which he ascribes to the benefits of the sea air, although the institution has no facilities for bathing in warmed sea water, which he thinks would be of immeasurable advantage in such cases. He also recommends the seashore in the winter as preferable in that climate, to the summer.

Physiopathology of the Suprarenal Capsules. G. LUCIBELLI.—Animals deprived of both suprarenal capsules rapidly succumbed, but after extirpation of one capsule, the animals continued to increase in weight with no disturbance in any function. Lucibelli also found that rabbits supported infection better after the removal of one capsule than before—the animals survived an infection to which all the control intact animals succumbed. When the infection was so severe as to be necessarily fatal, the animals with one capsule survived considerably longer than the intact animals. The exaggerated protective function displayed by the one remaining capsule was explained by the marked increase in size of the capsule left, and

its histologic alterations. Hyperplasia of the young cells was evident and augmented nutrition by the circulation in the cortical and medullary substance. Experiments with microorganisms inoculated into one capsule showed that the other capsule, under these circumstances, had no power to modify or conquer the resulting infection.

Lo Sperimentale (Florence) lv, 3.

Influence of Mechanical Causes on Development of Bones. G. BANCHI.—The results of an interesting series of experiments on animals indicate that the functioning of the muscles is an important factor in the development and shaping of the bones, on account of the mechanical irritation caused by their contractions.

Rhinoscleroma. U. MANTEGAZZA.—The inefficacy of treatment or surgical intervention in case of rhinoscleroma, suggests the advisability of trying serum treatment. Mantegazza's experimental research reported in this communication, confirms the specific action of the bacillus discovered by Frisch, as the causal agent of rhinoscleroma, thus providing a base for the production of an effective serum.

Queries and Minor Notes.

MEDICAL PRACTICE ACTS.

PALMERSTON, ONT., Oct. 30, 1901.

To the Editor:—Please answer in THE JOURNAL the following queries and greatly oblige: 1. What are the fees for license in Nebraska; when and where are the examinations held? 2. What are the fees for license in Michigan; when and where are the examinations held? 3. Where is Oak Park, a suburb of Chicago, situated with relation to the city proper? What is its population?

W. R.

ANS.—In Nebraska the fee for registration is $10. The board meets on the first Tuesday of each month at the Capitol Building, Lincoln. In Michigan the fee for examination is $10. Regular meetings of boards are held at Lansing on the second Tuesdays of June and October, each year. Application should be made at least two weeks before to the secretary, Dr. B. D. Harison, Sault Ste. Marie. Oak Park is directly west of Chicago, and is practically a continuation of its suburb wards, though not included. It is the largest village in Cicero Township; the population of the township was 16,310 in 1900.

PHARMACY AND MEDICAL LAWS.

CLEVELAND, OHIO, Oct. 28, 1901.

To the Editor:—Will you please inform me through THE JOURNAL to whom I should write to procure copies of the pharmacy and medical laws of the States of Arkansas and Colorado? C. H. G.

ANS.—Write to the Secretaries of State, Little Rock and Denver.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Oct. 17 to 23, 1901, inclusive:

Edward T. Comegys, major and surgeon, U. S. A., member of a board at Fort Meade, S. D., to determine the fitness of officers for promotion.

William M. Gray, major and surgeon, U. S. A., leave of absence extended.

Thomas G. Holmes, contract surgeon, relieved from duty as transport surgeon of the transport *Grant*, and on the expiry of his present leave of absence will proceed from Detroit, Mich., to Fort Walla Walla, Wash., for post duty.

Frank P. Kenyon, captain and asst.-surgeon, Vols., having tendered his resignation, is honorably discharged from the service of the United States, to take effect from this date, Oct. 23, 1901.

William F. Lewis, captain and asst.-surgeon, U. S. A., from Fort Leavenworth, Kan., to duty at Fort D. A. Russell, Wyo.

Irving W. Rand, captain and asst.-surgeon, U. S. A., leave of absence granted.

Alexander N. Stark, captain and asst.-surgeon, U. S. A., now on duty at Fort McHenry, Md., will proceed to Fort Monroe, Va., for temporary duty, October 21; also member of examining boards at Fort Monroe, Va., vice First Lieutenant Matthew A. De Laney, asst.-surgeon, U. S. A., relieved.

William A. Summerall, captain and asst.-surgeon, Vols., leave of absence granted.

Benjamin L. Ten Eyck, captain and asst.-surgeon, U. S. A., leave of absence on certificates of disability extended.

Samuel M. Waterhouse, lieutenant and asst.-surgeon, U. S. A., member of a board at Fort Meade, S. D., to determine the fitness of officers for promotion.

Henry E. Wetherill, lieutenant and asst.-surgeon, U. S. A., having been found incapacitated for active service on account of disability, which is not the result of any incident of service, is wholly retired, to take effect Oct. 16, 1901.

Eugene R. Whitmore, lieutenant and asst.-surgeon, U. S. A., member of an examining board at Fort Sheridan, Ill., during the temporary absence of Major Francis J. Ives, surgeon, U. S. A.

Appointments, Promotions, Retirements, Etc.,

of Army Medical Officers, recorded in the Adjutant-General's Office, between Aug. 15 and Oct. 15, 1901. Previous notices of this character were published in THE JOURNAL of Sept. 7, 1901. During the month ending September 15, the only changes recorded were the promotion of two regular medical officers to be surgeons, with the rank of major: Captain Eugene L. Swift, asst.-surgeon, dating from May 7, 1901, and Captain Paul Shillock, asst.-surgeon, dating from June 7, 1901.

During the month ending October 15, there were:

Regular Army, Appointments.—To be assistant-surgeons, with the rank of first lieutenant: Wilson T. Davidson, of New York, Sept. 5, 1901; George H. Crabtree, of Illinois, Sept. 5, 1901; George H. Richardson, of Pennsylvania, Sept. 9, 1901; Herbert M. Smith, of Virginia, Sept. 20, 1901; Evan P. Howell, of Georgia, Sept. 21, 1901, and Cosam J. Bartlett, of California, Sept. 21, 1901.

Volunteers, Honorably Discharged.—Captain Frederick H. Morhart, asst.-surgeon, Sept. 30, 1901, and Captain Meyer Herman, asst.-surgeon, Oct. 8, 1901.

Killed in Action.—Major Richard H. Griswold, surgeon, Sept. 28, 1901, at Balangiga, Samar, P. I.

Navy Changes.

Changes in the Medical Corps of the Navy, week ending Oct. 26, 1901:

Surgeon J. M. Edgar, ordered to the *Wabash*, October 23, as relief of Surgeon H. G. Beyer.

Surgeon H. G. Beyer, detached from the *Wabash*, upon reporting of relief, and ordered to the *Prairie*, when put into commission.

Asst.-Surgeon R. T. Atkinson, detached from the *Wabash*, October 30, and ordered to the *Prairie* when put into commission.

Asst.-Surgeon B. B. Kerr, ordered to the *Wabash*, October 28.

Asst.-Surgeon E. Thompson, ordered to the Naval Hospital, Boston, Mass., October 26.

Surgeon G. Pickrell, detached from the *Columbia*, upon reporting of relief, and ordered to the Naval Dispensary, Washington, D. C.

Surgeon P. Leach, ordered to the *Columbia*, as relief of Surgeon G. Pickrell.

P. A. Surgeon R. M. Kennedy, ordered to the *Franklin*.

Asst.-Surgeon A. G. Grunwell, ordered to the Naval Hospital, Norfolk, Va., November 1.

Asst.-Surgeon L. W. Bishop, ordered to the *Independence*.

Pharmacist H. Henry, detached from the *Independence* and ordered to the Bureau of Medicine and Surgery, Navy Department.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Oct. 26, 1901:

SMALLPOX—UNITED STATES.

California: San Francisco, Oct. 6-13, 3 cases, 1 death.
Kentucky: Lexington, Oct. 12-19, 2 cases.
Louisiana: New Orleans, Oct. 12-19, 5 cases.
Massachusetts: Boston, Oct. 12-19, 18 cases, 2 deaths.
Nebraska: Omaha, Oct. 6-19, 6 cases.
New Hampshire: Concord, Oct. 6-12, 1 case, 1 death.
New Jersey: Camden, Oct. 12-19, 6 cases.
New York: Oct. 12-19, Elmira, 6 cases; New York, 4 cases, 1 death.
Pennsylvania: Norristown, Oct. 12-19, 1 case; Philadelphia, Oct. 12-19, 69 cases, 10 deaths; Pittsburg, Oct. 12-19, 1 case; Steelton, Oct. 13-20, 1 case.
Rhode Island: Newport, Oct. 12-19, 1 case.
Utah: Salt Lake City, Oct. 12-19, 1 case.
Vermont: Burlington, Oct. 12-19, 15 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Sept. 28-Oct. 5, 4 cases.
Belgium: Brussels, Sept. 28-Oct. 5, 1 death.
Colombia: Cartagena, Sept. 23-29, 1 death; Panama, Oct. 7-14, 125 cases.
France: Paris, Oct. 5-11, 6 deaths.
Great Britain: London, Sept. 28-Oct. 5, 169 cases, 7 deaths; Southampton, Sept. 28-Oct. 5, 1 case.
India: Calcutta, Sept. 7-14, 2 deaths; Madras, Sept. 7-13, 2 deaths.
Mexico: Mexico, Sept. 29-Oct. 6, 2 cases.
Nova Scotia: Halifax, Oct. 6-12, 20 cases.
Russia: Moscow, Sept. 14-28, 5 cases, 1 death; Odessa, Sept. 28-Oct. 5, 2 cases; Warsaw, Sept. 14-21, 1 death.
Spain: Madrid, July 15-Sept. 9, 26 deaths.
Uruguay: Montevideo, Aug. 16-24, 22 cases, 2 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, Oct. 6-13, 1 case, 1 death.

PLAGUE—INSULAR.

Philippines: Manila, Aug. 18-Sept. 7, 13 deaths.

PLAGUE—FOREIGN.

China: Hongkong, Aug. 31-Sept. 7, 6 cases, 6 deaths; Newchwang or Newchang, Aug. 31, 2 cases.
India: Bombay, Sept. 10-17, 250 deaths; Calcutta, Sept. 7-14, 18 deaths; Karachi, Sept. 8-16, 18 cases, 13 deaths.

YELLOW FEVER.

Costa Rica: Port Limon, Oct. 5-12, 2 cases, 1 death.
Mexico: Merida, Sept. 21-28, 3 deaths; Valladolid, Sept. 21-28, 4 deaths; Vera Cruz, Sept. 28-Oct. 5, 7 cases, 4 deaths.

CHOLERA.

India: Bombay, Sept. 10-17, 11 deaths; Calcutta, Sept. 7-14, 8 deaths; Madras, Sept. 7-13, 113 deaths.
Java: Batavia, Aug. 31-Sept. 7, 80 cases, 68 deaths.

THE VALUE OF THROAT CULTURES IN DIPHTHERIA.*

M. H. FUSSELL, M.D.
PHILADELPHIA.

In no disease which the general practitioner has to treat is an accurate and prompt diagnosis of more importance than it is in diphtheria. It is practically undisputed that a true diphtheritic exudate is caused by the Klebs-Löffler bacillus. It is a fact now established and generally accepted that many of the diseases which have as a sign a membranous exudation in the throat are not diphtheria. It is also established that a true diphtheritic exudation may exist in other portions of the body than the throat, and it is well known that true diphtheria bacilli may exist in a throat free from any exudate, and in a person entirely free from clinical signs of any disease. Another important fact, long ago pointed out by Jacobi and other observers, is that true diphtheria, capable of transmitting the disease, frequently passes under the form and guise of some benign throat affection, usually follicular tonsillitis.

These facts have all been proven by the workers in bacteriology, aided by clinical observers. If these are well proven, have they aided the general practitioner in his daily work? Have they made it possible to distinguish these puzzling cases? If they have, are the means employed of such a character that they should be part of a routine practice? All these questions can be answered in the affirmative.

Soon after the recognition of the Klebs-Löffler bacillus, Baginsky published a paper in which he made enthusiastic claims of the value of throat cultures as an absolute diagnostic means of distinguishing cases of true diphtheria from those which simulate the disease. In the course of his article he remarked "that before long the use of throat cultures as a diagnostic means will be as common as the microscopic examination of the urine is to diagnose renal disease." For a time this belief was common, and throughout the entire country the various boards of health established centers from which culture-tubes could be obtained. At first these were used largely throughout the various cities, but soon fell into disuse to a great degree, this certainly being so in my district of Philadelphia, in which practice physicians who are always ready to avail themselves of every possible opportunity to make an accurate diagnosis.

The facts I have stated being true—that the bacillus of diphtheria is present in all cases of true diphtheria and that many membranous exudates are due to other organisms than the Klebs-Löffler bacillus—it would seem to always follow that Löffler's bacillus must always be found in a culture made from a case of diphtheria, and conversely in membranous exudates which are not true diphtheria Löffler's bacillus should never be found. This is true in the vast majority of cases, but it is not always so; that is, in certain cases of true diphtheria the bacillus diphtheriæ does not grow in the first culture made, and in certain cases which are not true diphtheria a bacillus which is extremely like if not a true diphtheria bacillus is found.

These cases are rare, but the class of cases in which there are no classical clinical signs of diphtheria, but in which true active, virulent diphtheria bacilli are found, is large. It is this latter class in which cultures are of the greatest possible value. It is also this class which it seems to me have made many men lose faith in this most valuable diagnostic test. This latter is because we are not all so wise and observing as Jacobi, who said long before the bacillus of diphtheria was discovered: "There are more cases of diphtheria walking about our streets than are confined to the houses." Also because practicing physicians are slow to recognize that a case of true diphtheria may recover in a very few days without treatment, and yet cause in another individual a fatal attack of the disease.

Another cause for disuse of cultures, at least those made by health boards, is that diphtheria bacilli remain in the throat of a patient who has suffered from diphtheria a long time, three or four weeks, after all clinical signs have gone, certainly so long in cases promptly treated with antitoxin.

In cities where the home is placarded under the same rules as they are in Philadelphia, physicians are not willing to keep their patients confined to the house as long as the bacilli are in the throat, and consequently do not use cultures.

I am quite certain that these are some of the reasons, though I think improper ones, for the disuse of cultures by the physicians of the writer's district. I take it that they probably hold good in other localities though I have no data to prove it. Of late years I have been making throat cultures in all throat exudates and have notes preserved of most of the results. The use of these cultures is of the greatest possible comfort to me, amply repay me, and are of much value to my patients.

I constantly carry in my pocket a tube of blood-serum and make a culture of every throat which is in any way suspicious. The value which I see in the use of these cultures will be best made clear by citation of certain cases; and by a statement which it seems to me will be borne out by all those who have had much experience in general practice, that is, that it is impossible to make a certain and accurate early diagnosis of diphtheria, either by the symptoms of the case, the location of the membrane, or the character of the exudate.

An early accurate diagnosis can be made by the use of cultures and the demonstration of diphtheria bacilli in

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank Billings, George Dock and J. M. Anders.

the culture. The following statements can be proven: 1. True cases of diphtheria may have few or no clinical symptoms. 2. Cases of tonsillitis or pharyngitis may have severe symptoms and be serious, but not true diphtheria, and consequently not able to transmit diphtheria. 3. A diphtheritic exudate may be easily detached and leave no bleeding surface. 4. An exudate due to some other organism may be a true membrane impossible to detach from the mucous membrane.

These statements are common knowledge, but I have notes many times repeated to prove them. A few will suffice.

CASE 1.—A boy, 7 years old, was affected with an exudate strictly confined to both tonsils and to the follicles of the tonsils. There was no fever, by careful observation. The pulse was not quickened and the appetite was good. Indeed, except for the tonsillar exudate the lad seemed entirely well. A culture made from the throat showed a pure culture of diphtheria bacilli. This was surely a true case of diphtheria as proven by the fact that his grandmother, who nursed him, contracted diphtheria of a virulent type.

CASE 2.—A male, about 16 years old, was suddenly seized with high fever, extremely sore throat, much swelling and engorgement of both tonsils, with a slight exudate easily removed. The case greatly worried me, but I was much relieved to find that a culture twelve hours old did not show diphtheria bacilli. Repeated cultures were also negative. The patient promptly recovered without specific treatment in three or four days.

CASE 3.—A little girl was seized with fever, sore throat and vomiting. On examination it was found that both tonsils were covered with a thick pultaceous exudate which was easily removed and left no bleeding surface. A pure culture of diphtheria bacillus was found in twelve hours. In this case three cousins with whom she played developed typical diphtheria, and bacilli were demonstrated in their throats.

CASE 4.—A young man entered my office with a patch of membrane on his uvula which it was impossible to detach. It appeared like a classical diphtheritic membrane. A culture was made and he was at once given antitoxin. No diphtheria bacilli grew, but a pure culture of staphylococci did. This was repeated in other cultures. No case of diphtheria developed from the young man.

In all these cases the presence or the absence of diphtheria bacilli allowed me to make a diagnosis within twenty-four hours. It is true that the results of all my cultures have not been so striking or so comforting, but these suffice to make my point.

Cases, such as the following, are rare, and when cultures are made by the health board and the case placarded, it is most annoying and disheartening, but if an error exists, it is on the safe side:

A married woman was seized with a sore throat, fever, etc. On both tonsils was an exudate which resembled that of ordinary follicular tonsillitis. In the first culture made there were many bacilli which looked just like diphtheria bacilli. In following cultures they were entirely absent. The child of the woman, who was constantly with her, did not develop diphtheria.

I suppose cultures can most surely and with less risk of mistake be made in the laboratories, but they can be made at home in our own little laboratories, which should exist if we expect to keep pace with the rapid strides of modern practice.

The necessary equipment is: 1, a good microscope with an oil-immersion lens, and the necessary working knowledge; 2, culture-tubes of blood-serum; 3, an oven with a thermostat; 4, stains, cover-slips and slides; 5, ability to recognize diphtheria bacilli when present. Necessarily, the use of these require skill, but when once acquired it is just as easy to examine a culture-tube as it is to examine a specimen of urine.

I presume that for a long time the practice will not become routine, but the sooner we come to it, the sooner we will be able to distinguish between these important and annoying cases. They but prove by their rarity the value of the habit of making cultures.

DISCUSSION.

DR. DE LANCEY ROCHESTER, Buffalo, N. Y.—I rise to second the position taken by Dr. Fussell and to state that I have found the taking of cultures in the throat a valuable aid in the treatment. It is my habit to take cultures from every sore throat that I see and, in many cases, the diagnosis of diphtheria has been made earlier than it possibly could have been in any other way. I think the value of the antitoxin is very great when it is administered early and in large doses. The treatment of diphtheria is not under consideration, but I would like to say that the use of antitoxin in large doses, 6000 units in thirty-six hours, gives us the best results, and without any unpleasant symptoms except, possibly, urticaria. In a suspicious case of diphtheria the taking of early and repeated cultures is very valuable. Not infrequently there is a pseudo-bacillus which resembles, in its anatomic characteristics, very closely the bacilli of diphtheria, and it has repeatedly happened that the board of health will report to us that the organisms very much resemble those of diphtheria, that it is very suspicious, and they ask for a second culture; this second culture, of course, will clear the matter up, but valuable time may be lost. To repeat the cultures I think is as valuable as to obtain the first culture.

In regard to the persistence of the organisms in the throat after the clinical manifestations of the disease have disappeared, I have experimented a great deal in different applications which will overcome that condition, and I have come to the conclusion that there are three agents of value in getting rid of these organisms early. The first of these is Loeffler's solution, which must be applied thoroughly and with a swab; spraying does no good; swab the throat well and but one or two applications will be necessary. It is an exceedingly painful application and so very difficult to apply to children's throats. I have had it in my own throat and I have never had such a painful sensation; it lasted about fifteen minutes. Therefore, I started to find another application. Nitrate of silver is but little painful to the throat, even when applied in strong solutions. I found that a 10 per cent. solution, if applied thoroughly, is fully as efficacious as the Loeffler solution; it should be applied with a swab and done thoroughly, and it will clear up the throat very rapidly. Then again I make it a practice to have the patients spray their throats with a 50 per cent. solution of peroxid of hydrogen, i. e., equal parts of the peroxid of hydrogen and water, and this is used regularly every three or four hours and, in this way, I get rid of the organisms rapidly.

DR. R. C. NEWTON, Montclair, N. J.—We had a mild epidemic of diphtheria in Montclair last March. Out of the first ten cases which developed in two or three days all were taking milk from the same dairy. The Health Inspector went at once to that dairy and took cultures from the throats of everyone who was engaged around the cows. There were 45 men employed in the dairy, and our of these, two were found who had the Klebs-Loeffler bacilli in their throats, and these two men were engaged in milking the cows. Afterwards 17 more of the milkmen showed the bacilli in their throats. The sale of the milk was promptly suspended and the epidemic ceased. The inspector by taking these cultures prevented an epidemic of diphtheria and probably a loss of a number of lives. Anti-

toxin was administered to every man at the dairy. Of course as these men milked they would infect the milk in the manner so well explained in Dr. Boston's paper, and this accounted for the spread of the disease. The New York City Board of Health took an interest in the matter and it was through their investigations that it was proved that the bacilli found in the throats of these milkmen were the true Klebs-Loeffler bacilli and were virulent. That the disease did not take more hold and we did not have more cases among the large number of families supplied by this dairy is explained by the fact that the bacilli will not grow at a temperature of 40 F. The milk at this dairy is cooled down to 40 immediately after milking and is kept so until delivered. Hence there was little chance for the bacilli to multiply, and only a few comparatively found their way into the throats of the milk-consumers.

DR. C. W. LILLIE, East St. Louis, Ill.—The question of the value of taking cultures from the throat is pretty well settled, but whether it is to be done for the benefit of the patient or not is not clear. I think the culture method will be of more benefit in the way of prophylaxis than it will be in the treatment of an individual case, and it is in that direction that we must expect its greatest benefits. The case referred to by Dr. Newton is an example of the value in culture-taking. If the boards of health were always careful, and always placed the matter in the hands of a competent person, a much greater benefit would be experienced, but this matter is usually left in the hands of politicians for certain reasons, who hand over the work to one specially favored by them, with the result that but little results are obtained. If this matter should be taken in hand by persons who are competent it would be a very useful method. I think it is the duty of the medical profession to urge upon the health authorities the necessity for making these cultures for determining the presence or absence of the bacilli and thus prevent the spread of this disease.

TOTAL RETROFLEXION OF THE IRIS.*

ALVIN A. HUBBELL, M.D.
BUFFALO, N. Y.

Cases of total retroflexion of the iris are of such rare occurrence that I venture to report the following:

A. G., German, aged 55, laborer, presented himself to me at my clinic at the Charity Eye, Ear and Throat Hospital, Buffalo, N. Y., on May 26, 1899. Two weeks previous to that date he had fallen from a wagon, and had struck the left side of his face and head against the pavement. He did not think that there was a stone or other object on the pavement against which he fell, but it seems quite probable to me that he was mistaken. According to the patient's statement, there had never been any injury or disease of either eye previous to this fall. Vision had been acute in both eyes, and the color of eyes and size of pupils had been alike. At the time of his first visit, the left eyelids were somewhat ecchymotic, and the episcleral tissues of the left eyeball were deeply congested, but there was no pain. The cornea was slightly hazy, the aqueous chamber was filled with blood, and the tension of the eyeball was somewhat diminished, although there had been no laceration of the sclera or cornea and not even an abrasion of the conjunctiva. The presence of blood in the aqueous humor prevented any view of the fundus from being obtained. A simple treatment, consisting in the occasional use of hot fomentations over the eye to favor the absorption of the blood, was prescribed, together with instillations of a saturated solution of boracic acid.

The right eye was normal in every respect. The pupil was of usual size and reacted well to light. The iris was bright and lustrous and of a rather deep-blue color. Both eyes were quite prominent in their orbits.

The blood in the aqueous humor of the left eye was gradually absorbed, and had quite disappeared on June 10. There remained, however, a quantity of dark-gray colored debris, which floated about in clumps and shreds, and which seemed to be attached more or less to the parts in the ciliary region. This debris also became absorbed, only a little of it being visible on June 23. At this time, no trace of the iris could be found, either by the use of focal illumination or the ophthalmoscope; neither were the ciliary processes visible. Without instrumental assistance, the blackness of the pupillary area was co-equal in size with that of the corneal disc, and the ophthalmoscope gave a reddish reflex of the fundus of the same diameter. The appearance, in fact, was that of total aniridia. Not only was there an absence of the iris, but the crystalline lens had also disappeared, and with + 10 D. vision equaled 6/60. There were still some opacities in the aqueous humor which somewhat obscured an ophthalmoscopic examination of the fundus, and I deferred my search for the crystalline lens to a later date.

In the course of a few weeks, the reaction had entirely subsided, the tension had become normal, all opacities had disappeared, and every part of the fundus accessible to ophthalmoscopic examination was perfectly clear and distinct; aside from the aphakia and the disappearance of the iris, there was no evidence of any deep-seated injury or disease. A careful search was then made, both by myself and Drs. Abbott, Howe, Grove, and other ophthalmologists, and we all failed to find the crystalline lens in the vitreous cavity or in any other part of the eye. It certainly had not been extruded from the eyeball, as there had been no rupture of the sclera, and it was concluded that after being more or less lacerated by the contusion, it had become rapidly absorbed.

As regards the invisibility of the iris, it was decided that this was due to its having been thrown backwards, throughout its whole extent, against the ciliary body. Had it been torn from its periphery, it would have been seen in some part of the eyeball, and probably at the bottom of the aqueous chamber. But not even the smallest remnant of it could be found either early or late in the case.

On February 16, 1900, a rough test gave vision equal to 5/12 with a + 11 D. spherical glass. A spherocylindrical combination might have brought the vision to a higher degree of acuteness, but the patient disappeared, and a further test has not been possible.

Reduced to its lowest terms, then, this case is as follows: a violent concussion of a previously normal eye, followed by aphakia and disappearance of the iris. The crystalline lens was either dislocated to a point where it could not be found, or else it had become absorbed. The latter supposition is the one I accept. The iris was thrown entirely out of view, and this could only be done, so far as I am able to determine, by being reflected back against the ciliary body.

The mechanism of retroflexion is very obscure, but in this case it evidently consisted, in part, 1, in the destruction of the posterior support of the iris by a laceration of the zonule in a large part of its extent, and thus permitting a sinking backwards of the lens whether lacerated or not; 2, in rupturing the pupillary margin of the iris, probably at several points, allowing this membrane to become easily turned back and super-

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

imposed over the ciliary body; and 3, after being torn at its pupillary margin, and thrown backwards against the ciliary body, the effusion of blood, which attended the lacerations, necessarily filled the space between the iris and cornea, and thus crowded upon the already reflected iris, and held it firmly in its new position till it became so fixed there that it could not replace itself.

This case is not only of interest as an example of an exceedingly rare traumatism of the iris, but it also shows how violent a contusion and injury may be inflicted on the eye, with remarkable lesions in the anterior portion of the globe, and yet useful vision be preserved.

REMARKS.

Retroflexion of the iris, otherwise known as inversion, introversion, retroversion, sinking in, disappearance, retraction, etc., of the iris, may be partial or total. The partial form may follow various traumatisms and certain operations in which the zonule has been ruptured, either with or without luxation of the crystalline lens. It has occurred in my practice in two cases during the operation of simple extraction of senile cataract, attended by rupture of the zonule and escape of vitreous humor. Passeur[1] records a case in which partial retroflexion occurred during an attempt to perform an iridectomy for seconday glaucoma, following luxation of the crystalline lens. Similar cases have been seen by others. A partial retroflexion of the iris has also been noted after contusions of the eyeball, and particularly after wounds of the cornea or sclera near the corneo-scleral junction, with rupture of the zonule and hernia of the vitreous body. But some cases have been recorded as partial retroflexion in the bibliographies of this lesion which undoubtedly belong to another class. For example, a case cited by C. Bell Taylor,[2] is not one of retroflexion, but a traumatic iridectomy in both eyes. No claim is made by the author that it was anything else. Eales and White[3] describe two cases of rupture of the sclera, with entanglement of the iris in the wound. These should not be regarded as retroflexions of the iris, as the description does not sustain such a diagnosis. It would be more proper to classify them as partial hernias.

Total retroflexion has a much greater interest than the partial form, inasmuch as it often occurs without any laceration of the cornea or sclera, and its mechanism is problematic. Von Ammon's case,[4] upon whose description the pathology of this lesion has up to the present time been based, was the first definite example of total retroflexion without laceration of the outer coat of the eye. The case of J. Adam Schmidt,[5] recorded in 1804, undoubtedly belongs to this class, but is indefinite in its history. Von Ammon's case marks the beginning of our real knowledge of this subject. In this case there were no external lesions of the eyes, yet in both there was total retroflexion of the iris.

Since this memorable report, only a small number of undoubted cases have been recorded. We may recall the following: Vose Solomon[6] reported a case in which there was total disappearance of the iris from contusion, with laceration of the sclera. A second one was by John Williams[7] in which there was injury of the eyes with complete loss of the iris and crystalline lens. A third case was by G. von Ottingen, of Dorpat,[8] caused by concussion of the eye, the iris disappearing and the crystalline lens, with its capsule, being dislocated into the vitreous humor. C. Bader[9] refers to a fourth case which was undoubtedly one of this lesion, and was probably caused by traumatism. The iris was apparently absent in an eye which had been blind for years and had a chalky lens rolling about in the hyaloid fossa. After excision of the eye, the iris "was found pressed upon the ciliary processes by aqueous humor." A fifth case was that of A. Samelson,[10] in which there was a total retroflexion of the iris, only a narrow border of it being visible. The ciliary processes were covered by this dark mass. L. W. Beardsley[11] describes a sixth case, seen on the fourth day after a contusion. There was a recent scar of the upper part of the cornea about 2 mm. from the limbus and about 3 mm. in length. The iris was invisible, and the crystalline lens became absorbed. With + 12 D. Sph. the vision ultimately reached 6/15. A seventh case was also mentioned in the same connection by Dr. Beardsley as occurring in the practice of Dr. C. Barck. In this case the eye was struck by a stone, and was seen a few days later. There was no external wound or cicatrix, either of the cornea or sclera. The crystalline lens was dislocated downward into the vitreous humor, and there was no trace of the iris. The fundus was just visible. Vision was about 6/50 with + 12 D. Sph. The case was only seen once.

Besides these cases, two or three others have been referred to by writers, but I have not yet been able to verify them, or to determine whether they are partial or total. This brief résumé, however, will suffice to show the infrequency of the lesion, and under these circumstances I may be pardoned for presenting to such a body as this the report of a single case.

TARSADENITIS MEIBOMICA.*

M. F. WEYMANN, M.D.
Professor of Ophthalmology and Otology, Central Medical College.
ST. JOSEPH, MO.

Definition.—A subacute or chronic infection of the Meibomian glands, tending to periodical acute exacerbations and, secondarily, altering the whole structure of the tarsal cartilages, chiefly the upper.

Etiology.—Diffusion through part, or all, of the Meibomian glandular system of chalazial disintegration products and their cause.

Pathogenesis.—Chalazia representing unhealthy granulation tissue of a very low type, scantily supplied with blood vessels, tend, from this nature of their make-up, to break down. The age of the patient and the condition of the general health modify this tendency to disintegration, great youthfulness and general debility favoring a destruction more or less acute, while more advanced age and good health favor chronicity. This circumstance is due merely to varying degrees of body resistance. Chalazia may, therefore, undergo, 1, suppuration; 2, chronic inflammatory softening.

1. Suppuration may be so severe as to bring about not only the destruction of the neoplastic tissue, but also of the tumor sac. This occurs chiefly in children and young persons and is the only method of spontaneous

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

cure. (This hint on the part of Nature should be noted under the head of treatment.)

More often the suppurative process fails to obliterate the sac and re-formation follows, though weeks and months may elapse before renewed chalazial construction begins and then another long period may go by before the small developing tumor is accidentally noticed. The suppurative process referred to does not lead to tarsadenitis, as, owing to its short duration, the discharge products soon find issue by means of perforation. This latter takes place almost invariably to the outside. Tension and distension, the chief causes of necrotic tissue destruction in spontaneous abscess drainage, are practically limited to the external lamina of the tarsal cartilage, as the eyeball supports, splint-like, the inner half.

2. Chronic softening is the type of chalazial disintegration. It does not begin, as a rule, during the formative period of the tumor, but after some growth has taken place which makes the problem of nutrition and resistance more difficult as the tumor-bulk increases. In this, it merely follows the example of other neoplasms (cancer, tubercles, gummata, etc.). With high powers of resistance the development of a chalazion may be very gradual and thus the tumor may enjoy a long period of exemption from its fate of disintegrating softening. But the vast majority show evidence (*q. v. infra*) of this process almost any time.

The disintegration products are very slowly formed and find exit through the excretory duct of a Meibomian gland, or a subconjunctival perforation. In either case the drainage is, owing to its scantiness, intermittent. The consistency of the discharge favors flow only under accumulation and consequent tension. During the intermissions, the drain openings become closed by clotted secretions in the form of an occluding pellicle resembling much a collodion film. Eruption takes place only after the accumulation tension overcomes the adhering power of the film. This latter is quite considerable, so that the drainage products have to lift off the pellicle by distension. This gives an appearance of a vesicle having undergone suppuration.

Drainage of this kind is not ideal on account of the intermittently pent-up discharges. The consequent local irritation soon converts the discharging track into a regular sinus with circumfistulous induration and unhealthy granulations about the orifice. A Meibomian duct engaged in this fistulous function is readily recognized by its nipple-shaped appearance. Above it, the observer will always detect, by palpation, a chalazion more or less disorganized and perhaps one or more secondary foci.

The reactive swelling often closes the duct in places and then discharge sacculations occur between the occlusions. Relief may come by subconjunctival perforations, after which the course of the fistulous duct is outlined by a purplish path along which small subconjunctival pus-lakes are observed like beads on a string. However, the inflammatory (necrotic) softening also occurs in the interglandular septa. Irruption into neighboring glands takes place and, by a repetition of this process, most, or all, of the upper cartilage may actually become detached into an anterior and posterior lamella from the destruction of the septal partitions. This brings about a clinical picture which I have called, on pathologico-anatomical grounds, *Tarsadenitis Meibomica*. The presentation of an example in the concrete being preferable to abstract statements, I here append a case.

Consultation by Mr. O. in the fall of 1899: Near the middle of the upper free border of the left lid a crater-like gland mouth; well above it, a degenerated chalazion, formerly the size of a pea, now not larger than a small shot; between it and the opening, another nodule hardly larger than a millet seed. Bulbar conjunctiva somewhat suffused, moderate photophobia, slight lacrimation, especially in the dust, sensation of fulness, heaviness and roughness, together with great itching and smarting about upper lid. The latter, considerably swollen, drooped and was tender to the touch. Eversion (painful) exhibited mushy swelling and lividity of conjunctival epithelium, a good deal of papillary roughness, and—a characteristic feature—an appearance simulating alligator leather, which was explained by the circumstance that the great inflammatory tumefaction over the infected glands made that surface stand out prominently, while the non-infected ducts, in the absence of swelling, looked like raphés between the infiltrated areas. In three different places were seen small grayish vesicles about the size of a pinhead. Puncture allowed the escape of a quantity of discharge hardly appreciable, but compression brought out a small drop. In places, the cartilage had thus been separated into two lamellæ, the inflammatory softening having admitted not only of irruption into neighboring glands, but of total removal of the septal tissue with free communication between distant intraglandular spaces. At the same time conjunctival perforation had occurred, the little vesicles being merely fistulous drains with their occluding pellicle distended.

A 5 per cent. solution of protargol injected into one perforation would freely emerge from the others. To get at the fountain-head of the trouble, I opened and scraped the tumor. For this purpose I used a minute spoon with spiculated border (I regret not to know the name of the inventor of this most excellent instrument) and found that I could freely curette between the separated tarsal laminæ, close up to the free border. After this procedure I continued lavage with the silver salt. All openings were injected, the duct orifice included, as there was found occasionally partial clogging from any one point.

This at once relieved the subjective complaints, though the reaction rather aggravated the swelling and the flow of pus for the first few days. It also changed the color of the morbid secretions from an ashen gray to a light yellow.

After three weeks neither pressure nor lavage produced pus, but the lid was still much thickened. In the absence of subjective symptoms, treatment was considered finished. It must be admitted, however, that from an idealistic point of view the cure was far from satisfactory, as the induration did not entirely disappear. This patient has had two relapses since: one in the fall of 1900, another in March, 1901. Incision emptied considerable muco-purulent discharge both times.

The case related allowed me, for the first time, to recognize the trouble and to determine its nature. I have since treated three more cases easily diagnosticated and thus have come to the conclusion that the affection is relatively frequent.

It is interesting to note how the master mind of the great clinician, Professor Fuchs, views this condition. He says in his text-book: "In particularly bad cases (of chalazion) an actual degeneration of the lids, especially the upper, takes place. The lids are thickened, and everted only with difficulty. The skin forms nodular projections, but can be displaced upon its bed and is not essentially altered, etc., . . . In such cases we might at first sight be disposed to think of tarsitis or a neoplasm."

He notes the presence of nodular projections in the skin, but hastens to add that the latter is not essentially altered. Now, as a matter of fact, the degenerated chalazia (and their secondary foci below them) do feel like nodules in the skin and seem to glide with it, but

critical examination with the tarsus steadied, demonstrates that they are not in the skin, but in the "cartilage." Incision proves both their location and structure. He says further: "Those chalazia which develop in the excretory ducts of the Meibomian glands assume a special appearance. They are then situated near the free border of the lid from which they project like a nipple."

He seems to take the nipple appearance for tumor eversion, when, as a matter of common observation, all chronic fistulous tracks develop a crown of proud flesh around the external opening. There is truth in the statement that a chalazion near the free border more readily produces this feature, but simply because the duct in this region is not as easily closed by reactive swelling and, therefore, continues its fistulous function more regularly than would a longer and thinner channel, as the latter is apt to establish auxiliary drainage by conjunctival perforations all along its route. Moreover, nipple orifices are common with chalazial tumors high up; in fact, a close situation to the free border of a primary chalazion is rather exceptional and, whenever one is observed there, it is mostly a secondary focus. Palpation above it will usually reveal the parent growth. Sometimes the latter has undergone degeneration and consequent elimination to such an extent that it is hardly any longer palpable, yet the tell-tale appearances of the conjunctiva settle the question even then. One will notice that the livid path marking the fistulous duct passes far above the secondary focus and ends in the characteristic discoloration marking the seat of the original neoplasm.

In an effort (for which I beg) to verify my statements, I ask of my readers some patience and attention, and in order to facilitate matters in the way of a first diagnosis, I ask indulgence for a diagnostic analysis: The drooping of the upper lid gives the patient a sleepy look and on account of the frequency of this sign in trachoma one is apt to think of this disease. However, the thickening of the lid should counsel caution. I do not mean to say that tumefaction is always absent in trachomatous drooping, but, when it occurs, it usually marks considerable inflammation, hence discharge, photophobia, lacrimation and bulbar involvement. This is precisely the point of difference in tarsadenitis, for the patient never complains of these spontaneously. He may, on suggestion, admit that light is not altogether agreeable and that his eyes water more readily in the dust, but the points he is quite insistent about are an annoying smarting and itching. Nor does the bulbus show any implication, unless it be a slight degree of venous congestion as we observe after a debauch.

A highly diagnostic point is the simultaneous presence on the free border of one or several "nipple orifices" of the Meibomian ducts. Their existence should not be inferred on account of small roundish elevations, for secretion plugs might produce them. A little pressure soon dissipates the doubt, as it empties the little amber-like pearls of Meibomian secretion. The fistulous nipple-mouth can not be squeezed out or wiped away. Moreover, it shows plainly inflammatory reddening, which may, however, be hidden under an occlusion pellicle. Palpation will reveal the shot-like granulomata.

The most valuable, in fact, pathognomonic, sign is the alligator-leather appearance of the conjunctiva lining the tarsal cartilage. The accumulation between the two tarsal laminæ of chalazial granulations and their morbid secretions not only causes distension, but also great inflammatory reaction of the subjacent conjunctiva, especially as the latter in this locality is closely adherent, almost after the fashion of a perichondrium. The consequent venous engorgement gives quite a livid color and a very marked swelling of the papillæ. The latter circumstance creates a very entrapping simulation of the papillary form of trachoma. In fact, I want to plead guilty personally to this very trap. Still, the raphé-like depressions over the undestroyed septa should, with their lighter (pinkish) hue, stay at once error in this direction. The remarkable thing is that stimulating applications (Cu SO4 in substance) actually give a sense of relief, nor is this strange when we consider the shedding of the proliferating surface epithelium.

Alligator-leather appearance, accompanied by much thickening of the lids and great smarting and itching, has always served me for an indication for incision, nor have I failed to drain away pent-up discharge. The subjective complaints then begin to cease at once. Another diagnostic feature is the presence of one or several vesicular elevations on the conjunctival surface filled with grayish or yellowish matter and about the size of a pinhead. They are capillary perforations with an occluding pellicle.

In exceptionally acute attacks external perforation takes place with subcutaneous abscess. The latter occurrence in the upper lid, especially toward the temporal part, should invite inspection as to the possible existence of tarsadenitis.

SUGGESTIONS FOR LESSENING THE FREQUENCY OF RELAPSES AFTER TREATMENT OF MORPHINISM.*

A. J. PRESSEY, M.D.

CLEVELAND, OHIO.

Every physician well understands that the percentage of relapses of patients treated for morphinism is large—just how large I do not know. In many instances it has been an absolute impossibility for me to keep track of the cases I have treated. During a correspondence with a physician a few months ago in regard to my treating his son for the morphin addiction, he wrote me that he knew that statistics proved that 95 per cent. of all patients cured relapsed. I have heard it stated that one can prove almost anything, except facts, by statistics. If the physician has the statistics to corroborate his assertion, I am prepared to believe the statement correct. It has been estimated by some who have had considerable experience that 50 per cent. of cases treated relapsed. I dare say that that is a fair estimate when all classes of cases are counted, but if we will eliminate the well-marked cases of degenerates I feel sure that the percentage will be far below the above estimate.

I believe that if those who treat morphinism could do as the careful surgeons sometimes do, select his cases and have full control of them until they are discharged by him, that he would be able to reduce the percentage to less than 25. All who have had experience I think will bear me witness that it is a most difficult thing to do, to retain a patient under treatment for a sufficient length of time after the morphin has been discontinued to regain a reasonable amount of physical and moral strength and tone.

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

Usually very soon after the morphin is entirely withdrawn the appetite is abnormally acute; sleep is sound and refreshing; the mental faculties are all buoyed up; their hopes, anticipations and expectations are all overdrawn; their confidence in themselves to withstand any temptation that can possibly come to them is much overestimated; they have no desire whatever for opiates; in fact, they believe that they are fully as unlikely to relapse as one who has never used opiates is to acquire the addiction. However, in case of pain from any of the ordinary ills of life, or if they allow themselves to become fatigued, mentally or physically, the temptation to relieve themselves just that once is very great. At this point there are many relapses. Had the patient remained in the institution for a few weeks longer or until he had regained more fortitude and strength of character he would probably have remained free of the addiction for the remainder of his life.

Another very frequent cause of relapse is the use of alcoholic drinks. I am convinced that there is scarcely an exception to the rule, that any person who has once been addicted to morphin will relapse sooner or later if he will allow himself to use alcohol as a beverage in any form or in any quantity.

He must be a total abstainer during the balance of his life. Tobacco in all forms appears to have a tendency to provoke a desire to use narcotics after having once been addicted to the use of them. And especially is this true with cigarettes where the smoke is inhaled as is customary with most cigarette smokers. In nearly all cases where I have been unable to induce patients to discontinue cigarettes while taking treatment or after being cured they have relapsed within a few months' time. Highly seasoned or stimulating food, any form of dissipation or excess may become the straw that breaks the camel's back.

The degenerates, depraved and vicious, furnish a large number of habitués, nearly all of whom, no matter how thoroughly they are treated, nor how well they are guarded, after treatment within a short time return to their former associates and loafing places and very soon begin using drugs again. Of course, there are some exceptions; once in a while one who appears the most hopeless will remain for years or for a lifetime without relapsing. I have in mind two or three of what appeared to be among the most hopeless cases that I have ever treated who have now gone over two years without returning to the use of the drug. Experience has taught me not to despair of any case that manifests a desire to be cured. It is also just as true that some of those who seem the most hopeful will relapse at the first opportunity.

There is a class of patients that relapse after a period of from three to eight months, which seem to be the least excusable of all. They leave the institution in a very good condition; their general health is apparently all that could be desired; they improve in flesh and strength; all their surroundings are favorable; they are pursuing their vocations with comfort and perhaps feeling better and stronger than for years; but, strange as it may seem, they have not learned that they can not take one dose and not take more. This one dose may be taken for some pain, real or imaginary; it may be for fatigue or a mental depression, or, as I have known it to be taken, simply to see if the effect would be as it formerly was. It seems very peculiar that one or two experiences of that kind would not be sufficient, but I have known instances where the same thing had been repeated time and again. It would appear that the only thing that can be done for this class of patients is to cure them as often as they relapse. It is unjust to say that they were not cured because of their relapse. We would not think of saying that a man was not cured of pneumonia because he had a second attack in three months or a year. A person is cured of morphinism when he does not desire or require morphin or any other drug to make him feel comfortable and well. Undoubtedly, the greatest safeguard that can be given a newly cured habitué is perfect health.

The plan or method of treatment that will come nearest to securing that end will have much to do with lessening the percentage of relapses. Physicians, I believe, have adopted one of three general plans for the relief of morphinism: 1, the sudden withdrawal; 2, the rapid reduction; 3, the gradual reduction. The first, the sudden withdrawal, we will only consider for the sake of condemning it. It is cruel in the extreme and is not without danger to life. I have known of only a few cases treated in this way and have known of one death by it. The symptoms which follow the sudden withdrawal of morphin from a person taking 10 to 30 grains in twenty-four hours, is always alarming, such as vomiting, diarrhea, profuse perspiration which the patient describes as feeling cold as ice-water, severe pains and cramps in the abdomen and calves of the leg, a peculiar, unbearable pain of the joints as though they were being pulled apart. The heart's action becomes very weak and rapid, running up to 140 and 160 or 200 beats per minute. There is also an indescribable nervousness which the patient usually declares to be the most unbearable of all. These symptoms may be followed by collapse and death or they will gradually subside after a few days and the patient finally recovers. However, I can scarcely imagine a physician that would be willing to apply such heroic measures to a patient who is already a physical and nervous wreck. I am very sure he would not consider such severe measures where milder means will secure as good or better results, at least in any other form of disease and especially so where the nervous system is involved.

The rapid reduction is little better. With this method the withdrawal is so rapid that we get nearly all of the abstinence symptoms that we have with the sudden withdrawal, although they may be somewhat modified and there is less danger of collapse, but the misery is longer drawn out. It might be argued that it would be well for the patients to suffer during the treatment, that there would be less inclination for them to return to the use of it again if they knew they must suffer severely to become free of it; but the facts I think will not sustain the argument. The severe strain and shock from that kind of treatment, added to an already injured nervous system, can only have a tendency to make the patient less able to withstand temptation. It must be remembered that withdrawing the morphin is not curing the morphin habit. Unless the patient is so far restored that there is not a constant desire felt for a narcotic he might as well not have had the morphin withdrawn. While the gradual reduction method as has usually been described and practiced is a decided improvement over either of the other two, it is not all that could be desired. To withdraw a certain fraction of a grain each day or to withdraw a certain fraction of the dose of the previous day is not a good method. When a certain amount is withdrawn each day regardless of the condition of the patient one would be cer-

tain to soon have some of the withdrawal symptoms manifest themselves. Unless the reduction is discontinued the appetite will disappear, sleep will be absent and the patient will be losing ground instead of improving. By the time the morphin is entirely withdrawn the patient will be very weak, much emaciated and extremely nervous.

It is possible by a modification of the gradual reduction method with a large proportion of patients to withdraw the morphin and have them feeling better during their entire treatment than while they were taking morphin ad libitum; also to have a majority of them improve in weight and strength and general health. These conditions undoubtedly will have a tendency to lessen the number of relapses.

The method that I practice in all cases is a form of gradual reduction and is graded in each individual case according to the condition of the patient. I take it for granted when a patient comes to me that he is taking more morphin than he requires to make him comfortable. This will be found true in nine cases out of ten. Nearly always where the dose is more than 10 grains per day he will be fully as comfortable on about one-half the quantity that he has been accustomed to use. If he should feel much discomfort from the amount withdrawn, at once increase the quantity sufficiently to secure comparative ease. I always give morphin four times a day to each patient and intend to give enough each time to keep them fairly easy until within an hour or so of the time to give it again. As an illustration we will presume that we have a patient who is taking 10 grains per day; we would presume he might be comfortable on 4 grains. Make a solution of 16 grains to the ounce and give 30 minims, which would represent one grain which we will give four times during the twenty-four hours. If we find that he is uncomfortable and shows any of the abstinence symptoms we will increase the quantity a few minims; if we find him comfortable after twenty-four or forty-eight hours withdraw one minim at each of the four doses. Continue the reduction each day until we find he is taking as small a dose as possible without feeling too much discomfort for more than an hour or so before the time for giving morphin again. When this point of discomfort has been reached we will rest for two or three days or until the patient is comparatively easy on the amount he has been receiving; then withdraw another minim and proceed in this manner until the amount has been reduced to 6 or 8 minims, when it is better to make a solution of 8 grains to the ounce and give twice the quantity, as a minim of the strong solution will represent a larger amount of morphin than we should be able to withdraw at one time without producing too much discomfort. Again, when this solution has been reduced so the patient is taking only 5 or 6 minims we make another solution of one-half the strength and give twice the amount and so on until he is not taking more than 1/120 grain at a time, when we try to discontinue it entirely.

In some cases it will have to be reduced to a much smaller quantity before it can be entirely withdrawn. Never discontinue the morphin while the dose is large enough so that the loss of it can be felt by the patient. During the entire withdrawal period and for a longer or shorter time afterward the patient should be built up with nerve tonics, heart tonics, and general tonics, a liberal diet, and as much sleep as possible. I have been using static electricity with several cases during the past year and I believe with great benefit to some. It has appeared to me to have a quieting effect on the nervous system. I also believe that it has had a decided effect on equalizing the circulation. Often when the patient is troubled with cold extremities a few applications of spray and perhaps mild sparks twice a day for a few days will entirely overcome the difficulty and there will be no further trouble. From the experience I have had with the static current I believe it to be beneficial as a nerve tonic in many cases and should be continued all through the treatment. I am inclined to consider it one of the most valuable single agents, if not the most valuable one, that we have in the treatment of morphinism, but I intend to give it a more thorough trial. No rules can be laid down to govern any particular case; the indications must be met as they arise, with each individual patient.

The physician who treats morphinism should devote his entire time to the watchful care of his patients.

Because of this need of minute personal supervision of the patient, the general practitioner fails and must continue to fail to attain the success reached in special institutions. The impression on the mind of the patient who goes away from home for treatment is always beneficial. He enters the institution expecting to be governed by the rules and regulations that control the other patients. He expects to be cured. He comes in contact with those that are cured and is encouraged. As a prevention of relapses I believe it better that each patient be permitted all the liberty during treatment with which he can be trusted. I am well aware that it is almost universally believed that an habitué can not be trusted at all and that they will take narcotics at every possible opportunity, but that is not my experience if he is made reasonably comfortable and has an assurance that at any time when he feels more discomfort from the lack of the drug than he is willing to endure that he can have enough morphin to relieve him. There is only a small percentage that will abuse the liberty given them. There are some who will take advantage of the least opportunity offered to procure a drug. Such must be confined to their rooms and closely watched But where liberty can be given they are better prepared to withstand temptation than where liberty has been denied. After patients have returned to their homes and have regained a sufficient amount of strength they should have pleasant employment and the companionship of congenial friends who will assist and encourage them.

Physicians called to treat patients who have once been addicted to the use of narcotics should be very careful to not give even the smallest amount of any form of an opiate, not even a little paregoric in a cough mixture. Legislation, to make it more difficult to procure morphin. would perhaps save some from relapsing as well as to prevent some from acquiring the addiction. With the best methods of treatment and all the safeguards that can be thrown around a patient there probably will always be some relapses, but that should not be used as an argument why all habitués should not receive treatment, and because one has relapsed is not a reason he should not receive treatment again.

DISCUSSION.

DR. T. D. CROTHERS, Hartford—The subject with which the paper treats is by no means settled, and there are no fixed rules and regulations that can be applied to every case. The method of reducing the quantity of morphin taken by these patients, whether rapidly or slowly, can only be decided by

the status of the particular case we have to deal with. I have seen cases where a rapid reduction of the drug proved entirely satisfactory. I think that when a man has been taking 10 or 20 grains of morphin daily, and the quantity has been reduced to one grain, we can cut this off entirely without waiting longer. There is a strong psychic element in these cases, and we should endeavor to gain full control of the mentality of the patient to succeed. Beyond 4 or 5 grains the amount of morphin utilized by the system is very small. A man may be taking 10 or 20 grains daily, but he does not get the full physiological effect of that sized dose. When I get a patient who is taking such a large dose, I immediately cut it down to 5 grains without letting him know the amount of the reduction, and later, in the course of a few days, I substitute some other alkaloid. There are so many narcotics that can be easily substituted for the morphin without causing the patient any particular discomfort. The greatest obstacle I have to deal with in these cases is to get rid of the needle fascination. When that is accomplished the case is more simple. To some persons the puncture of the needle is such a delight that it is very difficult to overcome it. No two cases of morphinism can be treated on the same lines. After the dose has been reduced to one grain, I usually withdraw the drug entirely and substitute some narcotic. In some instances I give a large dose of valerian or hops, and after a profuse sweat and bath the patient receives a hypodermic of pure water with the belief that it is morphin; as a result he will often sleep for many hours.

Dr. John Punton, Kansas City—My experience with morphin patients proves that the majority of them are suffering from malnutrition, and are greatly reduced in flesh as the result of the habit. I am inclined to think, therefore, that attention to the nutrition of the patient is just as important as the withdrawal of the drug, and that without the one the other is useless. Forced feeding is just as essential in these cases as in other neuroses. I would like to ask the essayist what he does to control the paroxysms at night.

Dr. A. J. Pressey, in reply—Dr. Crothers stated that he withdraws the morphin entirely when the dose has been reduced to one grain, and that the patients bear this very well. My experience is different. As regards the substitution of other narcotics, I have tried them all and found that in the end they prove just as bad as morphin. The drug which we employ as a substitute must, of course, be an opiate. The symptoms that result from the withdrawal of one grain of morphine are almost as severe as those following the withdrawal of 5 or 10 grains. I know that most men can be carried along quite as comfortably on 5 grains when their accustomed dose has been 10 grains. I had one man who was taking 120 grains of morphin and a large quantity of whisky daily, and I carried him along comfortably on 10 grains per day, in fact, he was much more comfortable than before, but to take away the last grain at one time has not proven so easy. Many of my patients could not stand the sudden withdrawal of the final 1-20th or 1-60th or even 1-80th of a grain, and the dose had to be reduced gradually to 1-120th and even to 1-240th of a grain.

Dr. Punton spoke of the value of forced feeding. This has never been found necessary in any of my cases. As soon as the morphin is withdrawn to such an extent that the patients feel comfortable, they will feed themselves, and they want about four or five meals daily. I always give a lunch at 10 p. m.—bed-time—and in addition to this many of the patients ask for a glass or a pitcher of milk to drink during the night.

INJURIES, FEIGNED AND REAL, WITH THEIR DIFFERENTIATION AND MEDICOLEGAL ASPECT.*

LAMBERT OTT, M.D.

PHILADELPHIA.

Injuries may be divided into two classes: 1, those with visible signs and symptoms; 2, those with invisible symptoms. Injury to certain tissues produce evidences of molecular change which usually justify the signs present and the symptoms complained of. A solution of continuity in either soft or bony parts requires no inductive or exclusive process of reasoning for their detection. Injuries to the nervous system productive of distinct objective symptoms, motor disturbances or discoverable sensory manifestations, do not tax the examiner's ingenuity to draw conclusions. Injuries to the nervous system, non-productive of objective symptoms in which the examiner is compelled to depend entirely upon subjective symptoms to arrive at the truth, are the most trying types the physician has to cope with. The invisible symptoms are the sensory, such as pain and the paresthesia. The visible symptoms and signs are chiefly motor and atrophic. Without repeating unnecessary detail as to the value of electricity and a thorough knowledge of the physiology of the nervous system, I will cite two cases, one of a common type and not difficult of diagnosis, the other in all its essentials surrounded by doubt because of the circumstances associated with the case, the presence only of subjective and the utter absence of objective symptoms.

A man is thrown violently to the ground and the only visible injuries are contusions to parts of the body, with the concomitant pains. The following day, apart from a slight soreness, the accident is dismissed. Subsequently the person injured notices that there is a gradual loss of power in one extremity confined to a group of muscles without disturbances of sensation. As time elapses the loss of power increases until a complete local palsy is evident. We are suddenly requested to state in how far is the injury real or feigned. Our first test is with the faradic current and feeble or no response follows. With the interrupted galvanic current we obtain contractions of the paralyzed muscles, but an altered response from the normal opening and closing contractions. Instead of obtaining the formula, CaCl is greater than AnCl, we have CaCl equals AnCl, or AnCl is greater than CaCl; in other words the reactions of degeneration. With such categorical evidence we state that the injury is real beyond any doubt whatsoever, and at once disprove the charge of malingering. Although where the important questions of liability and the degree of injury has arisen, the associated conditions, such as the nature of the injury, the locality of the contusions and the course of the case, must not be ignored. Here we have established facts which justify the most positive testimony, irrespective of the tribunal whether lay or medical.

On the other hand, a man claims to have been injured in a well-known accident, and, after spending the customary time in bed, whether for honest or other motives, on getting about complains of a continuous, localized pain, either along the course of the nerve, over the spine or in some other portion of the body. He describes the pain as follows: Persistent, continuous, with feeble re-

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

missions, and never changing its locality. He attributes it all to the injury sustained either many weeks or months ago. He presents absolutely no objective symptoms. We are again asked by persons upon whom the liability has been placed, in how far is his suffering real or feigned. Here is a more difficult and a different task from the preceding case.

First of all the fact that a monetary consideration may be involved should make us distrustful and resolved to ply every element of our resources either to confirm the truth of his suffering or unmask the deception. What are the methods which will lead us at least approximately to a conclusion? My experience teaches me that one can not have pain for a long period of time without producing some discoverable sign or change, however slight, which can not be detected either by the aid of electricity or our senses. There can be no pain without an involvement of sensory nerve fibers, whether it be in muscle, bone, cartilage or serous surfaces. Pains attributable to injuries are usually ascribed to the nerve or nerves. Let us suppose his injury was in the region of the shoulder and arm, involving branches of the brachial plexus with or without motor loss—the latter condition being readily ascertained by the reactions of electricity. If the complaint be one of pain only, covering a long period of time, and we find none of the characteristic associated conditions, are we not justified in denying that the person has pain?

In regions where persistent pain has been complained of we should find the following: 1, primarily an increased electro-muscular contractility and later a lessened electro-muscular contractility, a result uninfluenced by the patient's will; 2, an increased electro-sensibility, a result easily influenced by the patient's will; 3, a glazed, sometimes puffed and bleached, skin over the area of pain; 4, perverted nutrition of the hair follicles and nails over the region of pain; 5, possibly some muscular atrophy and flabbiness; 6, increased skin and muscular reflexes; 7, unnatural tremor induced by the effort to hold the member absolutely immobile; 8, general lowered nutrition necessarily produced by prolonged suffering; 9, hyperesthesia or anesthesia and variable sensibility to temperature, and 10, the locality of pain bears a close relationship to the distribution of nerves. It must be noted whether the pain and complaint conform to any of the well-known clinical types.

If we find the major part or all these signs and symptoms in a region presenting a persistent and prolonged pain the suffering is real. But viewing the complaint of pain, accompanied with normal surroundings, or conditions normally present under physiologic circumstances, such as, the natural electrical reactions, no abatement of the general health, no trophic changes, no paresthesia, or in other words, conditions found in those who do not complain of pain, are we not justified in branding the complainant as an impostor and charge him with malingering? Can a person have a persistent pain for a long period of time without producing some visible or palpable change in the surrounding tissues or in time affecting the general health? Pain in itself is a perverted sensation and impalpable, but the results of pain are often easily discovered. Because one complains of pain where a question of liability and damages are involved, it should not be said that he has not true pain.

Apart from the physical aspect of the presence and result of pain must be considered the fact that many people suffering injury, creating the question of a monetary responsibility, will semi-consciously malinger for selfish reasons and feign symptoms that are not readily perceptible to the senses. Hyperesthesia and anesthesia in the distribution of affected nerves are frequently observed. The esthesiometer, if carefully applied, will aid us materially. If the pain is remote from the distal part of the extremities, the esthesiometer will show an increased sensibility over the painful area, and the distal surfaces having normally a superior sensibility are now lower than over the area of pain. Tuerck and Trousseau, and later Nothnagel, assert that hyperesthesia is the primary manifestation in areas of pain, and is subsequently followed by anesthesia. Pain in a nerve or nerves does not always imply a marked disturbance of other part supplied by branches of this nerve. Hilton has taught us that the same nerve supplying the joints, and the amount of damages to be awarded. Let the lay-also supply the muscles moving the joint and skin over the insertion of the muscles. Inflammation of a joint produces rigidity of the muscles moving this joint because the same nerves supply the three different tissues involved; subjectively immobility of the joint surfaces is produced to lessen pain. A nerve in pain is an irritable and an irritated nerve and has in consequence all its functions heightened or increased. There is an unnatural flow of secretions when nerves are irritated, as is evidenced by an increased flow of saliva in facial neuralgia. A drastic or alkaline purge, irritating the intestinal mucous membrane nerve terminals, produces purgation; so should an irritable mixed nerve, supplying a cutaneous surface and the muscles beneath, likewise produce an increased or heightened function, discoverable both by electricity and other methods of examination.

MANNKOPFF'S TEST.

In this I do not have much faith, although Rumpf lays great stress on it in traumatic neuroses. It consists in observing the pulse rate before, after, and during pressure upon an area alleged to be painful. If the pulse becomes more rapid while the pressure is being made, it is supposed to be proof that the pain is real and has reflexly caused the heart to beat more rapidly. We can claim that if a patient complains of pain on the surface of the body it must be expressed by the nerves that reside there. There is no other structure that can express it, and somewhere in the course of its distribution between its peripheral termination and its central spinal or cerebral origin, the precise cause of the pain must be situated.

Pressure over painful areas should elicit pain, or some form of perverted sensation in nerve terminals; but, you will ask, can not any one wince under pressure and claim to have pain? This is a shortcoming in our examination, but, by suddenly detracting the patient's attention and then pressing on the supposed painful spot, you catch the patient unawares, and, if he is feigning, you are enabled to make deep pressure without obtaining evidences of pain. The changes observed in the skin overlying the painful area are atrophy, pigmentation and roughening. The atrophic skin appears smooth and more shiny than that of the other parts of the body. A change may also be noticed in the hair, a brittleness, coarseness, or unnatural grayness. The hair may have a tendency to fall out, or may grow denser along the course of affected nerves. The nails may be paler or discolored, transversely furrowed or have a diminished rate of growth.

Wherever the localized area of skin shows trophic disturbances, such as, atrophy or hypertrophy, congestion

or blanching, hyperesthesia or anesthesia, and its hair follicles altered either in quality or quantity, we may conclude that there lies beneath, either directly or indirectly, a nerve disturbance, and if a history of injury exists these changes should be ascribed to injuries of a nerve or nerves.

A species of modern robbery, which has grown to enormous proportions, is found in accident cases, and with these the neurologist is more or less associated. Modern transportation has greatly increased the number of accidents, and, as these cases are subject to jury trials in questions of liability and damages, an abuse has grown until the larger corporations often pay unjust claims rather than submit the question to a prejudiced jury. The professional injured and complainant for damages is a modern production and in our larger cities one-fourth of the cases possess this blackmailing character. The city electric lines lose from $300,000 to $500,000 annually and many of the cases are trumped up and pampered for the occasion by the unscrupulous collusion of lawyers and physicians, who agree to divide the gain among themselves. Observe very closely a damage suit at trial and note with what detail the complainant's case has been mastered and how some innocent perversion of function is enlarged and given an importance, how a trifle is made to appear as the most excruciating suffering and what a possible or positive permanency is attached to each disturbed function, to influence an ignorant set of laymen towards bringing a heavy verdict for the plaintiff. On the other hand, note the weakness of the defense in the utter absence of valuable medical testimony or a physician who has made but one examination and that in the latter part of the trouble, and who is now supposed to know as much about the case as the one in charge from the inception of the injury to the time of trial.

Seguin criticises our methods by saying that in this country claimants are very rarely subjected to scientific watching and repeated examinations. The physician or expert is expected to deliver an opinion after one or two interviews with the patient, so that the chances of detecting simulation are much reduced. A large corporation having many employes and many accidents should protect themselves by having a competent physician of their own choosing visit the injured at the earliest possible moment and subsequently as often as in his judgment he deems it necessary, so as to familiarize himself with the nature of the injury, the course of repair and recovery, and as to the degree of permanent injury. He could and should make these examinations in the presence of the attending physician at such time and place agreed upon, and, if proper notes are made, the corporation likely to be made the defendant is now armed with valuable testimony which not only forearms them when unjustly assailed, but in a measure has a restraining influence on those who seek to present physical conditions in a grossly exaggerated form. The knowledge on the part of the plaintiff that the defendant's surgeon has notes and information of his case from beginning to end would compel him, for his own safety, to confine himself to the truth and decidedly limit his prevarication. A large Philadelphia corporation sends its physician only after the case is reported convalescent and probably after all visible signs of injury have passed away. This weak position on their part puts them at the mercy of their opponents and from the many large and unjust sums mulcted from them one would imagine that they would alter their methods.

From a medical standpoint the prevailing methods of trial in injury cases are unscientific and productive of unjust results. In all cases there are two important elements to be considered; 1, as to the liability of the individual or corporation; 2, as to the degree and permanence of the injury and the amount of damages to be awarded. At the present time both questions are submitted for final conclusion to a lay jury, whose only guide as to the injury and its results and damages is the medical testimony which is often contradictory, misleading and unsatisfactory.

I hold that a better procedure would be to let a lay jury pass upon the evidence involving the question of liability, and, having this once determined, the medical testimony should be submitted to a jury of medical men to determine the degree and nature of the injury, its possible permanent influence on the future life of the injured, and, when this is finally settled, to have this same body of physicians fix the amount of damages to be awarded. Were a law of this kind enacted, there would be less robbery in accident suits, and careless and unscrupulous medical men, not confined to general practitioners alone, would be more chary in presenting their oftentimes biased and mercenary evidence.

Imagine a butcher, a baker and a dry-goods merchant passing judgment upon traumatic neuroses, such as paraplegia, neuritis, palsies, impaired vision and the various disturbances of locomotion incident to the graver accidents. How often in cases where the plaintiffs are women, who were but slightly injured or more likely not injured at all, is the hysterical or neurasthenic element produced.

Medical and expert testimony in accident cases is the opprobrium of the profession to-day, and the sooner such questions are considered from a scientific standpoint the greater the honor will be accorded to the medical profession. The physician is the only one that can differentiate the feigned from the real sufferer, and judiciously pass upon the nature and degree of the injury and the amount of damages to be awarded. Let the layman confine himself to questions of liability alone.

DISCUSSION.

DR. HAROLD N. MOYER, Chicago—If the suggestions made by Dr. Ott in his paper were all carried out, they would probably necessitate a change in the English Magna Charta and an amendment to most of the state constitutions in this country, if not to the Constitution of the United States itself. In communities with a jurisprudence derived from the English common law they are impracticable.

DR. LEO M. CRAFTS, Minneapolis—I can not subscribe to all the assertions made by Dr. Ott. That portion of the paper which referred to the differentiation between the objective and subjective symptoms frequently observed after injuries I consider admirable, but my experience does not agree with his as regards the amount of malingering by people who have been exposed to injury. I think his assertion in this respect is too broad and the result of observation from a biased standpoint. The statement that the plaintiff is more likely to be influenced by a moneyed consideration than the other party certainly does not obtain in the West; I do not know how it may be in the East. It is easy to understand how a corporation with large means can do more to influence litigation than can be done by a single individual whose means are usually limited. It has been my experience that these corporations frequently disregard the safety of their employes and the traveling public, and depend upon their wealth and influence to free them from just penalties for their neglect. I am thoroughly in accord with what Dr. Ott said regarding the desirability of a change in the legal procedure ordinarily followed in accident cases. If we could by some means obtain such modification of joint action as to make it possible to get impartial medical or

surgical testimony of an expert nature, it would do much to elevate the so-called "expert testimony" from the position of disrepute which it now occupies.

DR. RICHARD DEWEY, Wauwatosa—One point was not mentioned by the essayist, namely, the suggestive effect of the injury itself upon the patient, and, even more, the suggestive effect of an examination of the patient by the physician, especially if the latter asks him leading questions as to certain symptoms. The symptoms complained of by these persons may not be genuine, and still may not be dishonest. I have observed more than once a tendency to regard as dishonest all symptoms which are of a subjective nature and which can not be proven by objective means. Even in cases where the question of damages did not enter I have seen, as has every one experienced in these matters, serious impairment of function without demonstrable structural lesions.

DR. J. G. BILLER, Cherokee, Iowa—I have been unfortunate enough in two or three instances to be imposed upon by persons who claimed damages for feigned injuries, and who at once recovered when the damages were paid. I recall the case of a farmer whose reputation for honesty was excellent and whom I had known for years. He met with a railway accident, and I examined him, with the chief surgeon of the company, and in view of his symptoms, which had evidently been prompted by his attending physician, we made a favorable report. The railway company paid him $7000, and a few days after he had received the money the man was in town buying cattle. We should have some definite way of getting at these cases. They are often a disgrace to the profession. In the case I have referred to we made a very thorough examination, but we were unable to obtain any definite proof that the symptoms were feigned.

DR. HERMAN GASSER, Platteville, Wis.—So long as we cling to our present indefinite method of defining pain as subjective and objective, it will be impossible to formulate any system that will lead us to definite conclusions. There is no such thing as subjective and objective pain; there is only one kind, and that is pain. It is a psychical product. It always has some pathological basis for its production. In some instances the pathological lesion is easily discoverable; in others it is not. The reader of the paper referred to an increased pulse-rate as an indication of pain. Bichat showed long ago that this was a valuable sign as indicating the presence or absence of real injury or of pain. The significance of the pulse as an indication of health or disease can not be overestimated. If we see a sick or injured patient whose pulse is good and strong, no matter how badly he may claim to feel—he may even be in convulsions—still we can rest assured that there is no immediate danger. As regards the occurrence of symptoms, feigned and real, after the receipt of injuries, I recall the case of a girl who fell into an excavation while walking along the street. She was apparently not injured. Her relatives suggested that she ought to put in a claim for damages. She soon afterwards began to complain of pain in various parts of the body, and this was subsequently followed by the development of mental disturbance. She was examined by a number of physicians, and all of them, with one exception, thought she was hysteric. She finally recovered $2300 damages without the case going to trial, but this did not cure her, and she is still in a very poor condition both mentally and physically. She had a hysteric nervous organization and the advice of her fool friends made it chronically active, and she is now paying a severe penalty.

DR. F. SAVARY PEARCE, Philadelphia—I do not think the suggestions made by Dr. Ott regarding the methods of trial in these cases can ever be carried out, for the simple reason that the physician has nothing to do with the judicial side of the question involving the damages. The physician simply has to decide whether the person is injured or not, and this is often a very difficult question for the neurologist to answer. Having determined that the plaintiff is or is not suffering from a traumatic neurosis, either functional (which I do not believe in) or organic, then the evidence is given to the jury and the latter should make the award of damages.

DR. JOHN LEEMING, Chicago—My experience in the West confirms the experience of the essayist, and is not in accord with that of Dr. Crafts. The difficulty in ascertaining the condition of the patient previous to the occurrence of the accident has not been referred to. In cases where we can demonstrate the presence of structural lesions by actual measurement or by electrical tests there can be no suspicion of malingering, but the difficulty we have to deal with is to exclude positive shamming, or what I call "involuntary simulation," in persons who have received a trivial injury and who claim to be suffering from very serious neuroses. The nature of the injury is frequently out of all proportion to its effects, and these effects do not occur in cases where no litigation is pending. We should try to form a positive opinion regarding the true nature of these cases, and not hesitate to express it.

DR. LAMBERT OTT, in reply—Those who do not believe there is much rascality in connection with accident cases in large cities, I would invite to spend a brief period in Philadelphia and watch the jury trials, and I am sure they will become convinced. My suggestions regarding the method of trying these cases may not be practicable under our present statutes, but if they were adopted I believe the results would be far more satisfactory and just than by the present methods. I have studied this class of cases closely in Philadelphia and other large cities and the prevarication, distortion of facts, complaints of extreme suffering, with no visible evidence of disturbed tissue, associated with a history of trivial injury, make up the complexus of fraud presented for the purpose of mulcting corporations. I regret to say that in the trial of injury cases involving a large amount of damages you will often find the well-paid specialist on the side of the plaintiff with his biased statements giving strength and substance to their side. Large corporations are more just in the settlement of claims against them than individuals and whenever it is shown that they are justly liable they seek an amicable and fair settlement. Our courts in Philadelphia groan under the burden of such cases and only recently a band of conspirators were arrested and convicted for purposely meeting with accidents and subsequently feigning injury in order to extort damages from street railway companies. It is within the power of the medical procession to stamp out this rascality by condemning the malignerer and compelling all others to confine themselves to the truth.

SAMUEL FULLER—PILGRIM, DOCTOR AND DEACON.

I. N. DANFORTH, A.M., M.D.
CHICAGO.

"The names of those which came over first, in ye year 1620, and were by the blessing of God the first beginners and (in a sort) the foundation of all the Plantations and Colonies in New England; and their families."[1] So reads the quaint caption of Governor William Bradford's list of the *Mayflower* passengers, appended to his "History of Plimouth Plantation." Among the passengers, we read the name of "Mr. Samuell Fuller, and a servant caled William Butten. His wife was behind, a child which came afterwards."[2] Bridget Fuller, the wife of "Samuell," with a child who soon died, came over in the ship *Anne,* and landed at Plymouth in August, 1623; hence, both Samuel Fuller and his wife are properly classed among the "old comers" or the "forefathers," as the forefathers included all those who came in the first three ships; the *Mayflower,* the *Fortune,* and the *Anne.*[3] Referring again to Bradford's history, we read that "Mr. Fuller his servant dyed at sea; and after his wife came over, he had tow children by her, which are living and growne up to years (1650); but he dyed some 15. years agoe" (in 1633).[4] With these brief and quaint remarks, Bradford dismisses Samuel Fuller and his family.

Samuel Fuller's servant, William Butten (who was probably a student-assistant), who died at sea, November 6, 1620, as recorded by Prince;[5] and Bradford writes: "In all this viage ther died but one of ye passengers, which was William Butten, a youth, servant to Samuell Fuller when they drew near ye coast."[6]

There can be no doubt, I think, of the correctness of Packard's statement that "the earliest practitioner of medicine in Massachusetts was Samuel Fuller, who was among the passengers on the *Mayflower* in 1620."[7] It is probably also true, as stated by Packard, that "he held no medical diploma, nor was his position officially recognized"—i. e., by the "merchant adventurers," who were the financial backers of the pilgrims. Although, according to Palfrey, he came from London, it is not likely that he had pursued the study of medicine systematically. He must have joined the pilgrim company in Holland, as Palfrey states that he followed the occupation of a silk-weaver while the pilgrims lived in Leyden.[8] But they were all compelled to accept such employment as they could find in Holland, and they found it hard and up-hill work to earn even a scanty maintenance; in fact, this was one of the most persuasive reasons which led them to cross the then unknown ocean, and found the tiny republic, so memorable in the annals of civil and religious liberty. But diploma or no diploma, with or without "official" recognition, Fuller was practically and gladly recognized as the physician of the pilgrim colony, and was even called in a similar capacity by Governor Winthrop to the then infant colony of Massachusetts Bay on several occasions.

On reaching Leyden in 1611, according to Goodwin,[9] Fuller was chosen deacon in the pilgrim church, and was from that time forward a trusted leader and counsellor in all matters relating to the pilgrim church—spiritual, medical and secular. He also had a hand in the negotiations which resulted in the purchase of the *Speedwell* as one of the transports for the company across the Atlantic, as shown in the correspondence recorded by Bradford.[10] Goodwin states—I do not know upon what authority—that Fuller was one of the first "Board of Assistants to the Governor of Plymouth colony, continuing in office many years."[11] He was probably "assistant" in 1631, but this conjecture is based upon rather feeble evidence.

The first record of his professional work occurs in August, 1621, when in a scrimmage with the Indians "ther was 3. sore wounded; these they brought home with them," i. e., to Plymouth, "& had their wounds drest & cured and sente home."[12] This act of kindness had an excellent effect in the way of winning the friendship of their savage neighbors. In June or July, 1622, came the *Charity* and *Swan*, two ships sent by "Master Thomas Weston"—from whom the pilgrims suffered so much ill-usage—having in them some 50 or 60 men, and a very undesirable crowd they were. In fact they appear to have been a gang of tramps, chiefly interested in living without work, and they succeeded in foisting themselves upon the pilgrims for nearly two months, making sad havoc with the ears of green corn, which they stole and roasted and devoured, night and day, to the great damage of the growing crop, upon which the pilgrims were so dependent for the coming winter. During their unwelcome sojourn at Plymouth several of their number became "sick and lame,"[13] and these they left at Plymouth under Dr. Fuller's care, "although they had a surgeon of their own," Mr. Salisbury.[14] In the winter of 1628 an epidemic appeared among the newly arrived colonists at "Naumkeag" (now Salem), in Massachusetts Bay, caused "by infection that grue amonge ye passengers at sea, it spread also among them a shore of which many dyed, some of ye scurvie, other of an infectious feaoure" (fever), "which continued some time amongst them, though our people," i. e., at Plymouth, "through God's goodness escaped it."[15] Lieut.-Gov. Endicott of Naumkeag, having heard of Dr. Fuller of Plymouth, wrote Gov. Bradford "for some help, understanding here was one that had some skill yt way & had cured diverse of ye scurvie, and others of other diseases, by letting blood & other means."[16] Accordingly, Dr. Fuller was sent to the Bay colony, where he attended to the bodily ailments of the settlers, and also took occasion to make some explanations concerning the form of worship in use among the pilgrims, which removed some previous misunderstandings on that point. As a result of this visit, Gov. Endicott writes to Gov. Bradford, May 11, 1629: "I acknowledge my selfe much bound to you for your kind love and care in sending Mr. Fuller among us, and rejoyce much yt I am by him satisfied touching your judgments of ye outward forme of God's worshipe."[17] In the summer of 1630 Dr. Fuller was again called to Massachusetts Bay on account of the great prevalence of sickness, occasioned, says Gov. Winthrop, by "ill diet at sea." Therefore, on July 8, he went to Matappan (now Dorchester), "and let some 20 of these people blood." On August 4, he was at Salem, and a little later at Charlestown, probably still "letting blood" and discussing theology, for our good Doctor was quite as well versed in the theological squabbles of the day as he was in medicine. Soon after (in August?), we find him writing "the sadd news here is that many are sick and many are dead. I here but lose time, and long to be at home. I can do them no good, for I want drugs and things fitting to work with." Shortly, perhaps immediately, thereafter, Fuller returned to Plymouth, accompanied by Lieut.-Gov. Endicott. These visits of Dr. Fuller were potentially instrumental in initiating and cementing the close friendship which from that time forward existed between the "Old Colony" and the Colony of Massachusetts Bay.

In January, 1631, Henry Harwood, "a goodly young man" from Boston, was taken to Plymouth from a shallop wrecked on the Cape, and Dr. Fuller was obliged to "extend surgical treatment to him," says Goodwin, although the nature of the treatment is not specified.

This is the brief but suggestive history of Dr. Samuel Fuller's professional life so far as I have been able to trace it. But, of course, the quaint old records show us but an infinitesimal fraction of the work he actually did. We must picture him traveling back and forth from Plymouth to the sparse settlements of Massachusetts Bay, either on foot or in an open boat; or ministering to the manifold wants of the pilgrims during that first terrible winter (when half their number died), and for thirteen years afterwards; or visiting their savage neighbors, among whom a fearfully fatal epidemic raged for several years prior to and following the landing of the pilgrims and puritans. How primitive must have been his practice; how limited his medical and surgical armamentaria; how few and incapable the nurses at his command; what a lonely, isolated, depressing and dispiriting condition of things, for a physician burdened with such grave responsibilities! It is impossible for us physicians, situated as we are to-day, to apprehend or justly appreciate the poverty of knowledge and

methods by which he was environed. One can not help questioning whether those bold, hardy, fearless and resolute, yet self-denying and self-forgetting pilgrims, ever realized what vast and momentous results hung upon the success or failure of their wonderful experiment of self-government in church and state. Happily for us they triumphed; but who can estimate the consequences to civil and religious liberty, if they had failed!

But Dr. Fuller, as we have already seen, was also Deacon Fuller, and he was quite apt to have a hand in the theological squabbles which were so common in pilgrim and puritan days. In 1611, while the pilgrim church was still in Leyden, Deacon Fuller became involved in an epistolary controversy with one Daniel Studley—whom an old writer calls "that hypocritical chameleon"—and said Studley[18] "grinds his teeth against Samuel Fuller, a Deacon of Master Robinson's company; whom with his friends he describes as being ignorant idiots, noddy Nabalites, dogged Doegs, fair-faced Pharisees, shameless Shemites, malicious Michiavellians"—rather a choice assortment of alliterative expletives, from a "Ruling Elder" (Studley), to a Deacon (Fuller). It illustrates the fierce and uncompromising spirit of the times.

Deacon Fuller also had an eye to business, especially in the matter of the church collection, even in the presence of distinguished guests, as shown in the following description, by Governor Winthrop, of a church service in Plymouth in 1632: "On the Lord's Day," in the forenoon, "there was a sacrament which they did partake in; and, in the afternoon Mr. Roger Williams (according to their custom) propounded a question, to which the pastor Mr. Smith spake briefly; then Mr. Williams prophesied; and afterward the Governor of Plimouth (Bradford) spake to the question; after him Elder (Brewster); then some two or three men of the congregation. Then the Elder desired the Governour of Massachusetts (Winthrop) and Mr. (Rev. John) Wilson to speak to it, which they did. When this was ended, the Deacon, Mr. Fuller, put the congregation in mind of their duty of contribution; whereupon the Governor and all the rest went down to the deacon's seat, and put into the box and then returned."[19] How this contribution business would have delighted the soul of old John Wesley if he had been present!

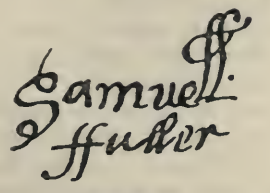
According to Rev. Edward Everett Hale, Dr. Fuller was one of the capitalists, or one of the "persons of largest means in the Leyden group of the emigrants";[20] but Dr. Azel Ames, in his recent work, says that "the good Doctor"—Hale—"is clearly in error."[21] * * * But Dr. Ames concludes that Dr. Fuller was "one of the Leyden chiefs, connected by blood and marriage with most of the leading families of Robinson's congregation. He was active in the preparations for the voyage * * * and doubtless one of the negotiators for the *Speedwell*."[22] In fact, he commenced the voyage in the *Speedwell*, but was transferred to the *Mayflower* after the *Speedwell* broke down, as the prospects seemed to warrant the conclusion that there would be an increase of "pilgrims" before long, and that a physician would be a rather important factor in the ship's company. With characteristic pilgrim forethought, Mistress Susannah White—sister of our Dr. Fuller—provided herself with a strong, solid, serviceable oaken cradle before leaving Leyden, and she took good care that the cradle (as well as her brother the Doctor), was safe aboard the *Mayflower* when at last she sailed away from the old to the New Plymouth. This cradle, after having rocked Peregrine White—first-born of American pilgrim babies,—and we know not how many other pilgrim babies—has descended to this day, as one of the few veritable and genuine *Mayflower* relics.

Dr. Fuller evidently did not believe that it was good for "man to be alone," as he was married three times. His first wife was Elsie Glascock, whom he must have married in England, but we have no certain data; she probably died in England prior to the removal of the pilgrim church to Holland. On April 30, 1613, he was married in Leyden to "Agnes Carpenter, maid, of Wrentham in England," daughter of Alexander Carpenter. but she did not live long, and, so far as I can learn, left no children. May 27, 1617, he was married to Bridget Lee, maid, of England, accompanied by "Joos" Lee, her mother,[23] the name "Joos" being the Dutch recording-clerk's spelling of some English pronomen, but what it was we can not now ascertain. Bridget Lee Fuller, as we have seen, did not accompany Dr. Fuller in the *Mayflower*, but followed in the *Anne* in 1623, bringing also their child, probably three or four years old; but this child died soon after they landed. Two other children, Samuel and Mercy, were born in Plymouth. Dr. Fuller's wife, Bridget, survived him many years, and was highly respected in Plymouth. She became quite famous as a nurse and midwife, and her services were much in requisition in this capacity.

In the year 1633, says Bradford, "it pleased ye Lord to visite them" (the pilgrims), "with an infectious fevoure, of which many fell very sicke, and upward of 20. persons dyed, men and women besids children, and sundry of them of their ancient friends which had lived in Holand; as Thomas Blossome, Richard Masterson, with sundry others, and in ye end (after he had much helped others) Samuell Fuller, who was their surgeon and phisition, and had been a great help and comfort unto them; as in his facultie so otherwise, being a deacon of ye church, a man godly and forward to do good, being much missed after his death; and he and ye rest of their brethren much lamented by them. and caused much sadness & mourning amongst them; which caused them to humble themselves & seek ye Lord; and towards winter it pleased the Lord ye sickness ceased. This disease allso swept away many of ye Indeans from all ye places near adjoyning, and ye spring before, espetially all ye month of May, there was such a quantitie of a great sort of flies, like (for bignes) to wasps or bumble-bees, which came out of holes in ye ground, and replenished all ye woods, and eate ye green things, and made such a constante yelling noyes, as made all ye woods ring of them, and ready to deaf ye hearers. They have not by ye English been seen or heard before or since.*

But ye Indeans tould them sickness would follow, and so it did in June, July, August, and ye cheefe heat of somer."[24]

Thus died Samuel Fuller the pilgrim "phisition" and deacon. It is much to be regretted that we can not know more of this pioneer physician of the "Old Colony." His will seems to indicate that he was a teacher as well as a doctor and deacon, as he directs that "Elizabeth Cowles, who was submitted to my education by her father and mother at Charlestown, to be returned to her parents;" and the same disposition to be made of "George Foster being placed with me by



* Bradford here describes a visitation of the cicada septendecem, or seventeen-year locust, the first account of its appearance in New England.

his parents still living at Sagus" (now Lynn); and "Widow Ring submitted to me the oversight of her son Andrew." He gives vent to his affection for Roger Williams as follows: "Whatsoever Mr. Roger Williams is indebted upon my books for physic, I freely give him." We also find this curious bequest: "I give to the Church of God at Plymouth the first cow-calf that my brown cow shall have."[25] While there are some uncertainties regarding this gift, when we realize that heifers were then (1633) worth £13 in Plymouth, and that the purchasing power of a pound sterling was four times greater than it is now, we shall see that the church might be pardoned for "indulging a hope" of fruitfulness on the part of Deacon Fuller's brown cow after all.

He left a library of twenty-seven volumes, says Goodwin, but does not enumerate them. Dr. Azel Ames remarks: "One is surprised and amused that the library of the good Dr. Fuller should contain so relatively small a proportion of medical works (although the number in print prior to his death in 1633 was not great, while rich in religious works pertinent to his function as a deacon" (Loc. Cit. p. 216); and then with provoking reticence, he fails to mention the "medical works" which Dr. Fuller did possess.

"Indications show that he was a man of intellect and good presence, it not being improbable that he was of regular education. He is among the noblest and most interesting of the pilgrims, and the regard of his descendants should secure him a fitting monument on that sacred hill where he prayed, and now sleeps in a grave of which 'no man knoweth.' Surely the zeal of his successors in the healing art might well provide some memorial of the good physician's excursions of mercy to the pestilential cottages of infant Salem, Dorchester and Boston."[26]

In conclusion, I append a facsimile of the autograph of Dr. Fuller, for which I am indebted to that monumental work, "Winsor's Narrative and Critical History of the United States." In place of an initial capital "F" he uses "ff," as was the frequent practice in those days.

ENFORCEMENT OF MEDICAL LAWS DEPENDENT ON AN ORGANIZED PROFESSION.

T. J. HAPPEL, M.D.
SECRETARY TENNESSEE STATE BOARD OF MEDICAL EXAMINERS.
TRENTON, TENN.

The question of medical legislation has been an open one for a time sufficiently long for thinking men of the profession to have become thoroughly conversant with it, but every member of an examining board soon becomes aware of the fact that many physicians in states having good laws by which to regulate the practice of medicine, know practically nothing about them. In some cases a few of the best men of the profession openly oppose medical legislation, laying down the broad proposition that every man should be allowed to do as he pleases in this free land of ours, employing if he wishes any one claiming to be a practitioner of medicine regardless of qualifications. Others take the position that the possession of a diploma from a medical college in so-called good standing and the registration of this diploma should be the only requirement demanded of them, taking the broad ground that the possession of such diploma is proof that the holder of it is better qualified for his work than the average member of an examining board.

These are samples of the objections presented. This diversity of opinion among physicians regarding medical laws interferes much with their enforcement. "In union there is strength," is more applicable to this condition of things in medical legislation and the enforcement of medical laws than any other possible thing. The old adage, "doctors disagree," is constantly flung in the faces of the medical profession when the enforcement of medical laws is urged. Violations of these laws are reported to the prosecuting attorney of the state or county, and he frequently replies that whilst Dr. M. desires the laws enforced, Drs. N. and P. do not want any such thing done and he is unwilling to enter upon the prosecution of the violators of medical laws.

This is especially the case when the prosecuting attorney is a salaried officer. His compensation is neither increased nor diminished by his enforcement of laws, and as the enforcement of any laws, new ones especially, and medical ones more particularly, may make him enemies and hence lose him votes in his next election, he is too well satisfied to do as little work along such lines as possible. In many instances these irregular and non-registered, law-infracting physicians live in a country district where they control a class of voters, or in a city they belong to the advertising class who pay the daily or weekly papers to exploit their wonderful skill as physicians and surgeons, and as a result it is the part of a business policy for the attorney to let them alone. These facts are set forth thus plainly that those who desire so to do may understand some of the difficulties met with by examining boards in having medical laws enforced. In other cases, a physician writes to the board notifying it that Dr. A. is violating the medical law, but that his name must not be used in prosecuting him as it would render him unpopular with Dr. A.'s friends, a thing that he can not afford to do as he expects to fall heir to Dr. A.'s work when he is driven by

the law out of the practice. The informant is willing to give names of parties for whom Dr. A. prescribes, and then leave the board to do the rest, or have it done as best they can.

This brings us directly to the consideration of the best method of the enforcement of the medical laws. We are ready to assert that they can not be enforced except through and by the medical profession, and it is a self-evident proposition that in such matters individual effort amounts to but little. A single physician, acting alone, unaided by others in the same neighborhood or county, could avail almost nothing in the enforcement of medical laws. He would be regarded as a troublesome, envious fellow, and unless he were willing to spend his own funds freely, could accomplish but little. To grapple successfully with the enforcement of our medical law there is needed a united, organized profession. In my experience as secretary of the Tennessee State Board of Medical Examiners, in those counties in which there exists a live, active, working, well-organized county society, infractions of the medical law are few, and at long intervals. A well-organized county medical society is regarded by the best class of citizens as reflecting the interests and wishes of the medical men of the county, and also as including in its folds, as a rule, the medical talent of the county. This fact gives it a weight and influence which as a society it can exert in many ways, when the individual members would fail in the accomplishment of anything. The request to the prosecuting attorney of the county by his county medical society that he vigorously prosecute Dr. A., would be at once effective, where individual effort would prove perfectly futile. A county medical society, as an organized body, would have great weight with politicians, as well as prosecuting attorneys, so that if our laws were non-effective, members of the law-making body in those counties where these societies are active would promptly ask what was wanted, and would readily undertake to secure it for them. Where there are no such organized societies, the profession is handicapped and can exert no influence except of a personal character. Too many physicians hold aloof from all political and other meetings, desiring to be neutral on all questions, but such a policy generally meets the fate it deserves—a complete failure.

Medical men should be not only physicians, and human beings, but also model citizens, and as such should take an active part in the every-day affairs of life. They should be the leading citizens of their respective neighborhoods, and as such, coupled with a well-known and well-understood professional organization, their influence would soon become great. With a live, active county society in every county in the state, medical laws can be enforced. An evildoer would not leave one county and move into another and practice in open violation of the law, because an organized profession is prepared to make him comply with the law in each county. The step taken by the American Medical Association in adopting the report of the Reorganization Committee and accepting the new Constitution and By-Laws arranged by that committee, will prove to be of incalculable advantage to the medical profession of this country, if the state societies reorganize in accord with the suggestions connected with this report. If this is done the state societies must be composed of only such members of the medical profession as are in good standing with their respective county medical societies. No one then can be a member of the American Medical Association who is not connected with and in good standing in his state society, and no one can hold membership in his state society who does not belong to his county society, so that the county society, or its equivalent, the oldest recognized society of the county, becomes the unit of measure for organized medicine. This is exactly as it should be. No one should be received by a state society who is not acceptable to, and does not belong to his county society, because the county society knows him best, and if he is fit to become a member of organized medicine, it will gladly accept and enroll him in its membership. Many men have crept into the American Medical Association who do not really belong there. Under our new laws they must be dropped or enter in by the way of the county medical society.

With the profession fully organized medical laws become as easy of enforcement as other laws. The medical profession will not be composed alone of individuals, but will become an organized and compact whole, the county members being the units of the county societies; the county societies, the units of the state societies; and the state societies, of the American Medical Association. Hence, what is asked by a county medical society becomes the demand of the state organization and then of that of the Nation, and the request or demand of the soon-to-be 20,000 or 40,000 members of the medical profession will have some weight even in National affairs.

In this state (Tennessee) there are about 4,000 practicing physicians. Of this number 400 are members of the state society, while about as many more belong to the different county and district societies representing organized medicine in this state. Under our new rules and regulations the strength (numerical) of the state society will be doubled, and of course its influence will grow.

No one can hesitate about demanding that medical laws be enforced, as the call can be made upon the county society to look after all violations within their bounds, and the society acting as an organized body can and will undertake the duty assigned it without bringing upon itself any opprobrium.

The enforcement of medical laws interest chiefly physicians, not the general public, and from a common business standpoint it becomes the duty of the profession to see that the laws do not become nonentities upon our statute books. It may be necessary in many cases to employ special attorneys to aid the prosecuting attorney. If this is done by the county medical societies, and the expense met out of the funds either of the state society, or the examining board, or out of the fines assessed against offenders, the laws can be easily enforced. Evildoers, unlicensed practitioners, would soon fold their tents and seek more profitable and congenial climes.

The success of this method of procedure has been clearly demonstrated by the Kentucky Board, when an attorney was employed at a salary to rid the state of all quacks plying their trade contrary to the laws. If this can be done by one attorney, how much more rapidly and effectively can the same thing be accomplished when the county medical societies, representing organized medicine, zealously proceed in a similar way. The profession of each county knows who is violating the law, and can reach such an one promptly, whilst if they delay and report the matter to the state society or the state board of examiners, much valuable time is lost. The local medical profession, whilst inaugurating the prosecutions to enforce medical laws, are merely representing

the medical profession of the state and are not subject to the opprobrium so much dreaded by many of the "holier than thou" members of our profession. In this way and this way alone can medical laws be enforced, and when enforced, not in a vindictive, malevolent manner, but simply for the good of the whole people, will be universally approved.

DIFFICULTIES MET WITH IN ENFORCING STATE MEDICAL LAWS.

BEVERLY D. HARISON, M.D.
Secretary of the Michigan State Board of Registration in Medicine.
SAULT STE. MARIE, MICH.

The penal sections of medical acts are not only very similar in the different states, but they have their constitutional authority from the power of the legislatures to enact laws covering what is known as the police power of the state. They are, therefore, on the same plane as other state laws, for instance, the law regulating the sale of liquor or the laws covering violence against the person, etc. Consequently, it is the duty of the prosecuting or district attorney to enforce a medical law just as precisely and strictly as it is customary for him to prosecute persons guilty of a crime against property or the person. The prosecuting or district attorney under the law has no authority given him to select what laws he shall enforce or to adjudge one legislative act necessary and another unimportant. All state laws are equally necessary and important from the standpoint of his duties under the law.

The above is an exact statement of a prosecuting or district attorney's duty in the matter of enforcing all state laws, including medical laws. But duty under the law is one thing and practice quite another thing. The majority of prosecuting or district attorneys are influenced in the view of their duties by the circumstances surrounding them in their respective districts, and while many of them conscientiously endeavor to enforce what they consider popular and necessary laws, still, when it comes to enforcing laws which in their judgment are unimportant and unpopular, they refuse or neglect to make use of the legal machinery at their disposal and insist upon methods not contemplated by the legislatures. As an illustration, an open and continuous violation of the liquor law comes to the notice of the district or prosecuting attorney. The information reaches him that a person is running a saloon and selling liquor without the necessary license. Does he wait until a licensed saloon-keeper swears to a formal complaint before taking any action? No. He instructs the sheriff, his executive officer, to investigate and lay a complaint at once. On the other hand, he is informed that a certain person in his district is publicly displaying the usual sign of a physician and surgeon and is practicing medicine without being registered according to law. Often times he has exact information concerning the party complained of from the executive officer of the board of medical registration in the state. Instead of instructing the sheriff in the matter he assumes an air of injured innocence and states his willingness to prosecute if some reputable citizen will step forward and swear to a formal complaint, or in other words, he says "I am perfectly willing and eager to do my duty under the law if I am compelled to do so. This quack complained of has a great many friends, ergo, votes, and I can square myself with these friends at the proper time, but I must on no account set the law in motion of my own violation through channels contemplated by law, *id est*, the sheriff and his deputies, otherwise I shall be held responsible by the party complained of." We all of us know of the injury accruing to the medical man who swears out a formal complaint against an illegal and unqualified medical practitioner in his district. The law never contemplated that a law-abiding and reputable citizen should be injured in the process of enforcing any law, great or small. It has provided the machinery for the enforcing of laws whether important or unimportant, and it is the duty of the prosecuting or district attorney to use this machinery irrespective of whether the law that is violated is popular or unpopular, important or unimportant.

The present attorney general of Michigan informs us that the above statement of a prosecuting or district attorney's duty is a correct interpretation of his duty under the law. Experience as an executive officer of a medical registration board leads us to believe that the greatest difficulty met with in enforcing medical laws is because of the apathy and ignorance of his duties, if nothing worse, of the ordinary prosecuting or district attorney, and the principle at fault lies in the method of creating such prosecuting or district attorney, i. e., the elective method. In Ontario, where the appointive method is in vogue, and where the prosecuting or district attorney holds office during good behavior only, all state laws, great or small, including the medical law, are enforced to the letter. Information to a crown attorney in a confidential way that a person is practicing medicine illegally is invariably followed immediately by investigation and arrest. A reputable physician in the same field is not made responsible for an unscrupulous and disreputable rival's downfall. The appointive prosecuting or district attorney does not attempt to evade responsibility in enforcing the law, but rather takes credit to himself for not only doing his duty but his whole duty. Under our elective system and covering only a two years' term, there is of necessity a great deal of "trimming" done by the ordinary and everyday prosecuting or district attorney. His duty consists in doing those things that will not harm any of his chances for renomination and re-election. Of course, it is not possible to change our system to the appointive one under our constitution. It is incumbent, therefore, for us to "cut our cloth" to the best advantage. A great deal in the right direction can be done by the state legislatures conferring larger powers and means upon the attorney-generals of the states. A rigid and frequent inspection by the attorney-general's department of the prosecuting or district attorneys would go a long way towards remedying the difficulties encountered now in enforcing medical and other important acts.

Another very important factor met with in enforcing state medical laws is due to the ignorance of physicians and citizens generally relative to the duties of prosecuting or district attorneys under the law, and also the duty of residents of a district towards insisting upon the district or prosecuting attorney doing his whole duty. An executive officer of a medical board is generally in receipt daily of letters of complaint from physicians giving information concerning the practice of an illiterate and unlicensed practitioner, accompanied by the statement that in the writer's opinion "the law is of no earthly use, otherwise the party or parties complained of would not be permitted to practice." They seem to be ignorant of the fact that a law can be ever so stringent but may be practically useless in a district if the citizens of

such district elect and keep in office a prosecutor who neglects to do his whole duty under the law, and they forget that as citizens they also have duties to perform; that it is not the law but the local administration of the law that is at fault.

Prosecutions started by medical boards or by medical men are liable to misinterpretation by the great mass of the people, and, therefore, to a greater or less extent lose their force; usually such prosecutions are unpopular and the only remedy for this is for the state boards and medical men generally to devote their energies towards compelling the prosecuting or district attorneys to do their duties under the law. They should advocate a more conscientious enforcement of all laws; also, they should hold a prosecuting or district attorney solely responsible for the non-enforcement of laws, and endeavor to have an attorney nominated and elected who will conscientiously do his whole duty with respect to the enforcement of all laws. No legislature has the power to create penal clauses of a medical act of such quality that they will take care of themselves, for their enforcement in a very large measure depends upon the ability and conscience of the prosecuting or district attorney, who is, under our constitution, the guardian and administrator of all state laws.

LAWS REGULATING THE PRACTICE OF MEDICINE IN THE VARIOUS STATES AND TERRITORIES OF THE UNITED STATES.

Below will be found a résumé of the conditions or legal restrictions of medical practice in the several states and territories of the United States. The frequent inquiries that are made to THE JOURNAL as to these points convince us that a digest of the medical laws of the states, brought as nearly up to date as is possible, will be appreciated. We have given verbatim in many cases the sections of the law that are of special interest, and in all cases have endeavored to state the essential facts. Recent legislation is given in full, so far as it pertains to medical practice. In all cases where possible, the abstracts or quotations have been submitted to the secretaries of the several examining or licensing boards and embody their corrections. In only one or two states have we failed in this, on account of lack of response to our repeated inquiries, but in these cases the facts are given from other presumably reliable sources. In many states the locality in which the examinations take place is not fixed, but is changed from time to time at the convenience of that particular examining board. For further information in practically all cases it will be advisable to communicate with the secretary or executive officer of the board at the address given.

ALABAMA.

Examination by state or county board is required of all candidates for license. Examination must be in writing and comprise ten different branches, viz., chemistry, anatomy, physiology, natural history, diagnosis, surgery, mechanism of labor, obstetric operations, and hygiene and medical jurisprudence. Materia medica and practice are intentionally omitted. Examinations are conducted by a paid supervisor not a member of the board. Every written examination by a county board is reviewed and reported upon by the state board. County boards can only examine candidates having diplomas from reputable medical colleges. There is no such restriction on the state board. An average of 75 per cent. is required to pass. All physicians, of whatever school, are examined alike.

Failure to pass a county board precludes any subsequent examination by any county board within twelve months, but appeal may be taken at once to the state board, which will give the candidate a new examination. The licenses must be recorded in the probate office of the county. By resolution of the state board of examiners, members of the faculties of medical colleges are forbidden to serve on county examining boards when graduates of their respective colleges are applicants.

The standard of qualifications, subjects and methods of examination, etc., are regulated by the State Medical Association, the board of censors of which forms the "state board." The fees for examination are $10 to the supervisor and $1 for registration in probate office. Dr. W. H. Sanders, state health officer, Montgomery, Ala.

ARIZONA.

The Territorial Board of Medical Examiners, 3 regulars, 1 homeopath and 1 eclectic, appointed by the governor, meets on the first Mondays in January, April, July and October, at Phoenix, to examine candidates for license. The examination of each applicant is conducted by the members of the board of the school of the practice represented by the diploma presented for inspection to the board.

"Section 1. . . . A diploma regularly issued by a medical college properly and lawfully organized under the laws of the state or territory wherein said college shall be located," is essential.

"Section 2. It shall be unlawful for any person to practice medicine, surgery or obstetrics in Arizona, unless such person shall have passed a satisfactory examination before the examining board hereinafter provided; and provided, further, that the provisions of this act shall not apply to women who have practiced obstetrics; provided, further, that the provisions of this act shall not apply to resident practicing physicians or surgeons, who have already complied with the present existing laws."

Sections 3 and 4 prescribe the appointment and organization of the board of examiners, the fee of $5 for examination, which shall be the only compensation of the board, etc.

"Section 5. Any person shall be regarded as practicing medicine who shall profess publicly to be a physician, or who shall prescribe for the sick; but nothing herein contained shall be construed to prohibit gratuitous services in cases of emergency, or for a physician or surgeon of the United States Army in the discharge of their duties as such; but none of the provisions of this act shall apply to those who are now and who have heretofore legally practiced medicine in Arizona.

"Section 6. Any person violating any of the provisions of this act shall be guilty of a misdemeanor, and upon conviction thereof shall be fined in any sum not less than $100, nor more than $1000, or by imprisonment in the county jail for a period of not less than three months nor more than one year, or by both such fine and imprisonment at the discretion of the courts."—Revised Statutes, 1901.

Secretary of board of medical examiners, Dr. Wm. L. Woodruff, Phœnix. All examinations shall be written, and on the following subjects: Anatomy, physiology, chemistry, materia medica, surgery, practice of medicine, obstetrics, gynecology and nervous diseases; a failure to secure an average of 75 per cent. on three or more subjects causes rejection.

ARKANSAS.

By the law of 1895, boards of medical examiners shall be appointed by the respective county courts, each consisting of three educated physicians, two of whom must be graduates of a reputable medical college; in counties including two judicial districts two boards may be appointed. These boards are authorized to examine any resident of the county who desires to practice medicine, and if they find him qualified, to grant a certificate entitling him to practice in the county or other counties into which his practice shall extend, as long as he remains a resident in the county where the certificate is issued. The fee for examination is $6. This apparently applies only to non-graduates, as June, 1901, registration of diploma with the county clerk is, we are informed, sufficient.

CALIFORNIA.

The new California law provides for a board of medical examiners, 9 in number, 5 elected by the Medical Society of the State of California, and 2 each by the State Homeopathic and Eclectic State Societies. The regular meetings of the board to be held the first Tuesday of April, August, and December; examinations of applicants for certificates may be held at other times and places under the supervision of any one member, the questions and answers to be submitted to the whole board for action thereon. Special meetings may be called by the president.

"Section 5. Every person before practicing medicine or surgery, or any of the departments of medicine or surgery in this state, must have the certificate herein provided for. In order to procure such certificate he must produce satisfactory testimonials of good moral character, and a diploma issued by some legally chartered medical school, the requirements of which medical school shall have been at the time of granting such diploma in no particular less than those prescribed by the Association of American Medical Colleges for that year; or he must produce satisfactory evidence of having possessed such diploma, or a license from some legally constituted institution which grants medical and surgical licenses only upon actual examination, or satisfactory evidence of having possessed such license; and he must accompany said diploma or license with an affidavit stating that he is the lawful possessor of the same, that he is the person therein named, and that the diploma or license was produced in the regular course, either of instruction or examination, without fraud or misrepresentation of any kind. Such affidavit may be taken before any person authorized to administer oaths, and the same shall be attested under the hand and official seal of such officer, if he have a seal. In addition to such affidavit, said board may hear such further evidence as, in its discretion, it may deem proper as to any of the matters embraced in said affidavit. If it should appear from such evidence that said affidavit is untrue in any particular, or if it should appear that the applicant is not of good moral character, the applicant must be rejected. In addition to the requirements above set forth, each applicant for a certificate must be personally examined by said board as to his qualifications to practice medicine and surgery. The examination shall be conducted in the English language, and shall be, in whole or in part, in writing, and shall be on the following subjects, to-wit: Anatomy, physiology, bacteriology, pathology, chemistry, pathology and toxicology, surgery, obstetrics, materia medica and therapeutics, and theory and practice of medicine. When the applicant applies for examination in materia medica and therapeutics, and theory and practice of medicine, he shall designate in what school of medicine he desires to practice, and only the member or members of the board who belong to the school so designated shall participate in this part of the examination. Examinations shall be practical in character, and designed to discover the applicant's fitness to practice medicine and surgery. Examinations in each subject shall consist of not less than ten questions, answers to which shall be marked upon a scale of one to ten. If an applicant fails in his first examination he may, after not less than six months, be re-examined. If he fails in a second examination he shall not thereafter be entitled to another examination in less than one year after date of second examination, and shall be

required to pay for such examinations the full fee. The examination papers shall form a part of the records of said board, and shall be kept on file by the secretary. In said examination the applicant shall be known and designated by number only, and the name attached to the number shall be kept secret by the secretary until after the board has finally voted upon the application. The secretary of the boart of medical examiners shall in no instance participate, as an examiner, in any examinations held by the board; nor shall he be entitled to vote upon the question of granting any certificate to practice medicine and surgery. Said board may, in its discretion, accept and register, upon payment of the registration fee, and without examination of the applicant, any certificate which shall have been issued to him by the medical examining board of the District of Columbia, or of any state or territory of the United States; provided, however, that the legal requirements of such medical examining board shall have been, at the time of issuing such certificate, in no degree or particular less than those of California at the time when such certificate shall be presented for registration to the board created by this act; and provided, further, that the provisions in this paragraph contained shall be held to apply only to such of said medical examining boards as accept and register the certificates granted by this board without examination by them of the ones holding such certificates. Each applicant on making application, shall pay to the secretary of the board a fee of $20, which shall be paid to the treasurer of said board by said secretary."

"Section 6. When any applicant has shown himself to be possessed of these qualifications herein required, and has successfully passed the said examination, a certificate must be issued to him by said board, authorizing him to practice medicine and surgery in this state. Said certificate shall be signed by the president and secretary of the said board, and sealed with the seal of the board."

"Section 8. Every person holding a certificate authorizing him to practice medicine or surgery, or both, in this state, must have it recorded in the office of the county clerk of the county in which the holder of said certificate is practicing his profession, and the fact of such recording shall be endorsed on the certificate by the county clerk recording the same. Every such person, on each change of residence, must have his certificate recorded in the county to which he shall have changed his residence. The absence of such record shall be *prima facie* evidence of the want of possession of such certificate. And any person holding a certificate who shall practice medicine or surgery, or attempt to practice medicine or surgery, without having first filed his certificate with the county clerk, as herein provided, shall be deemed guilty of a misdemeanor, and shall be punished by a fine of not less than $25 or more than $100, or by the imprisonment in the county jail for a period of not less than 30 days nor more than 60 days, or by both such fine and imprisonment."

Refusal or revocation of certificate may be for unprofessional or dishonorable conduct, which is defined as follows: 1. The procuring or aiding or abetting in procuring a criminal abortion. 2. The obtaining of any fee on the assurance that a manifestly incurable disease can be permanently cured. 3. The wilfully betraying a professional secret. 4. All advertising of medical business in which grossly improbable statements are made. 5. All advertising of any medicines, or of any means, whereby the monthly periods of women can be regulated, or the menses re-established if suppressed. 6. Conviction of any offense involving moral turpitude. 7. Habitual intemperance.

"Section 16. The following persons shall be deemed as practicing medicine or surgery within the meaning of this act: 1. Those who profess to be, or hold themselves out as being engaged as doctors, physicians or surgeons in the treatment of disease, injury, or deformity of human beings. 2. Those who, for pecuniary or valuable consideration, shall prescribe magnetism or electricity in the treatment of disease, injury, or deformity of human beings. 3. Those who, for pecuniary or valuable consideration, shall employ surgical or medical means or appliances for the treatment of disease, injury, or deformity of human beings, except dealers in surgical, dental and optical appliances. 4. Those who, for pecuniary or valuable consideration, prescribe or use any drug or medicine, appliance, or medical or surgical treatment, or perform any operation for the relief or cure of any bodily injury or disease. The doing of any of the acts in this section mentioned shall be taken to be *prima facie* evidence of an intent on the part of the person doing any of the said acts to represent himself as engaged in the practice of medicine or surgery, or both, but nothing in this act shall be construed as to inhibit service in case of emergency, or the domestic administration of family remedies; nor shall this act apply to any commissioned officer in the United States army, navy, or marine-hospital service, in the discharge of his professional duties, nor to any legally qualified dentist when engaged exclusively in the practice of dentistry, nor to any physician or surgeon from another state or territory, when in actual consultation with a legal practitioner of this state, if such physician or surgeon is, at the time of such consultation, a legal practitioner of medicine or surgery in the state or territory in which he resides; nor to any physician or surgeon residing on the border of a neighboring state and duly authorized under the laws thereof to practice medicine or surgery therein, whose practice extends within the limits of this state, provided, that such practitioner shall not open an office or appoint a place to meet patients or receive calls within the limits of this state."

Secretary board of medical examiners, Dr. C. C. Wadsworth, 1104 Van Ness Ave., San Francisco.

COLORADO.

The first three sections of the law of 1881 established and provided for a board of medical examiners, nine in number, "physicians of ability and integrity, graduates of respectable medical colleges," 6 regular, 2 homeopathic and 1 eclectic, to be appointed by the governor.

Section 4 provides that applicants for license, if graduates, must present their diplomas to the state board for verification, or furnish other evidence of graduation from a legally chartered medical school in good standing (requiring as a condition of graduation attendance upon four courses in four separate years, and adopting a standard similar to that of the Association of American Medical Colleges). Non-graduates must be examined by the board, and if the result is satisfactory will also receive a certificate.

Section 6 prescribes the fees $5 for certificate to graduates and $10 for examination, in advance. Section 7 prescribes the subjects of the examination, which may be altogether or partly in writing, viz., anatomy, physiology, chemistry, pathology, surgery, obstetrics and practice of medicine—exclusive of materia medica and therapeutics.

Section 8 requires recording of certificate with county clerk. Section 10 authorizes refusal or revocation of certificates for cause and Section 11 defines practice "any person shall be regarded as practicing medicine within the meaning of this act who shall profess publicly to be a physician and prescriber for the sick or shall attach to his name the title of M.D., or surgeon or doctor in a medical sense. But nothing in this act shall be construed to prohibit gratuitous services in cases of emergency."

"Section 14. The state board of medical examiners shall meet as a board of medical examiners in the city of Denver on the first Tuesday of January, April, July and October of each year and at such other times and places as may be found necessary for the performance of the duties."

"Section 15. (Amendatory.) No person shall be deemed to have violated the provisions of this act or the act of which it is amendatory who has complied with provisions on their part; and it shall be the duty of the state board of medical examiners to issue certificates to all persons authorizing them to practice medicine in this state who shall have complied with the provisions of this act and the act of which it is mandatory, including graduates of the electropathic school without prejudice, partiality or discrimination as to schools or systems of practice of medicine. That only courts of record in the State of Colorado shall have jurisdiction over and power to enforce the provisions of this act."

Secretary board of medical examiners, Dr. S. D. Van Meter, Denver.

CONNECTICUT.

According to the act approved May 25, 1893, the state board of health was empowered to appoint three examining committees on the nomination of the Connecticut Medical Society, the Connecticut Homeopathic Medical Society and the Connecticut Eclectic Medical Association, respectively, and to designate when and where said committees should hold examinations. Since 1897 all applicants to practice medicine or surgery must be examined in anatomy, physiology, medical chemistry, obstetrics, hygiene, surgery, pathology, diagnosis, and therapeutics, including practice and materia medica. Each committee shall frame its own questions and conduct its examinations in writing, and both questions and answers are filed with the state board of health. Each applicant shall have the right to choose which of the three committees shall be the one by whom he shall be examined; but before taking such examination he shall pay to the committee their expenses, not exceeding, however, the sum of $10. An applicant, after having been rejected by any of said examining committees, shall not be eligible to examination by another committee of examination until after the expiration of twelve months.

This year (1901) the law was amended again by the General Assembly in the following particulars: "The examinations are fixed at three specified dates annually, on the second Tuesdays of March, July and November, at such places as the committee may designate, and such additional meetings may be held as they may determine. Midwives are also examined, through the aid of an interpreter when necessary. The fee for examination is raised to $15 for general practice, but retained at $10 for examination for midwifery only. No person is eligible for examination for general practice unless he has received a diploma from some legally incorporated medical college. The registration of any practitioner may be revoked and canceled if convicted of any crime in the practice of his profession, or of a felony."

The definition of the practice of medicine as given in the law is: "No person . . . shall, in this state, for compensation, gain or reward, received or expected, treat, operate or prescribe, for any injury, deformity, ailment, or disease, actual or imaginary, of another person, nor practice surgery nor midwifery, unless or until he has obtained a certificate of registration as hereinafter provided, and then only in the kind or branch of practice as stated in said certificate."

There are, however, numerous specified exceptions, including dentists, emergency cases, employes of United States in the scope of their duties, physicians from outside as consultants in treating special cases, the recommendation of trademarks, proprietary remedies, sun cure, mind cures, christian science, or anyone else not prescribing drugs, poisons, medicine, chemical, or nostrums. Secretary state board of health, Prof. C. A. Lindsley, M.D., New Haven.

DELAWARE.

Delaware's law resembles in some features that of Pennsylvania. There is a medical council consisting of the chief justice of the state and the presidents of the two state boards of medical examiners. These boards are appointed by the governor from lists submitted by the Medical Society of Delaware, and by the Homeopathic Medical Society of Delaware State and Peninsula. Each consists of five members representing their respective state societies. Certificates for license to practice medicine are issued by the medical council to those who pass a satisfactory examination upon questions selected by it from lists furnished by the boards.

"Section 13. From and after the passage of this act any person not heretofore authorized to practice medicine and surgery in this state, and desiring to enter upon such practice, shall deliver to the secretary of the medical council, upon the payment of a fee of $10, a written application for examination, together with satisfactory proof that the applicant is more than 21 years of age, is of good moral character, has obtained a competent common school education, and has received a diploma conferring the degree of medicine from some legally incorporated medical college. Applicants who have received their degree in medicine after the passage of this act must have pursued the study of medicine for at least four years, including three regular courses of lectures in different years, in some legally incorporated medical college or colleges prior to the granting of said diploma. Such proof, if required, shall be made upon affidavit. Upon making of said payment and proof, the medical council shall issue to said applicant an order for examination before such one of the state boards of medical examiners

as the applicant for certificate may select. In case of failure at any such examination the candidate, after the expiration of six months and within two years, shall have the privilege of a second examination by the same board to which application was first made, without the payment of an additional fee, but if after six months and before two years from such examination said application shall be withdrawn the said $10 shall upon demand be returned."

"Section 15. The clerk of the peace of any of the counties of this state shall issue a license signed by the governor and countersigned by the secretary of state and sealed with the seal of this office, certifying that such person is authorized to practice medicine and surgery in that state, conformably to the laws thereof, to any person who shall present to him a certificate as provided in this act, or who shall have been qualified in one of the counties of this state prior to the passage of this act, and to no other person."

"Section 16. The provisions of this act shall not apply to physicians who are practitioners of any other state coming into this state in consultation with any lawful practitioner of medicine and surgery in this state."

Penalty for illegal practice: fine of not more than $500 or less than $100 or imprisonment not exceeding one year. A supplementary act passed April 18, 1895, provides:

"Section 1. The Medical Council of Delaware may refuse to issue a certificate for a license to practice medicine or surgery or may revoke a certificate issued for a license to practice medicine for the following causes, to-wit: Chronic and persistent inebriety, the practice of criminal abortion; conviction of a crime involving moral turpitude or for publicly advertising special ability to treat or cure chronic incurable diseases, or where any person shall present to the said medical council any diploma, license or certificate that shall have been illegally obtained or that shall have been signed or issued unlawfully or under fraudulent representation; in complaints for violating the provisions of this section the accused person shall be furnished with a copy of the complaint and given a hearing before the said medical council in person or by attorney."

"Section 2. Applicants examined and licensed by, or who are, or have been members of state examining and licensing boards of other states, upon the payment of $50 to the treasurer of the Medical Council of Delaware and on filing with the secretary of said medical council a copy of his or her license or certificate certified to by the affidavit of the president and secretary of such board, showing also that the standard of requirements of the said board at the time the said license or certificate was issued, was substantially the same as that required by the said Medical Council of Delaware, and of his or her affidavit as to the personality thereof, may be granted a certificate for a license to practice medicine and surgery by the said medical council upon the recommendation of the said board of medical examiners without further examinations thereby." (Reciprocity has been established with new Jersey.)

"Section 3. The state treasurer shall pay the sum of $300 per annum, in quarterly payments of $75 each, to the treasurer of the Medical Council of Delaware, who shall apportion and pay the same to the members of the said boards for their necessary expenses, and in addition $5 per day for each member for every meeting attended, but said per diem shall not exceed in any one year more than $25."

The applicant must be at least 21 years of age, must have a competent common school education and must have a diploma conferring the degree of Docter of Medicine from some legally incorporated medical college. Applicants who have received their degree since the passage of this act must have pursued the study of medicine for at least four years, including three regular courses of lectures in different years, prior to the granting of said diploma. Applicants must furnish satisfactory proof of good moral character. The examinations are conducted in writing. The boards of examiners meet at Dover on the third Tuesday of June, and the second Tuesday of December each year. The sessions last three days. No provision is made for granting unexamined candidates permits to practice in the intervals between the meetings of the boards of examiners. Subjects examined upon: Anatomy, physiology, hygiene, chemistry, surgery, obstetrics, practice of medicine, pathology, diagnosis, therapeutics, and materia medica. Examination fee, $10. P. W. Tomlinson, M.D., secretary of the medical council, Wilmington. Applicants must present their diplomas to the board.

DISTRICT OF COLUMBIA.

The District Commissioners appoint a board of medical supervisors consisting of the presidents of the examining boards and two others not physicians, one of whom shall be learned in the law; also three examining boards of five each, all physicians, one of the regular school and one for each of the other schools, homeopathic and eclectic, the two latter from lists made up by the homeopathic and eclectic societies respectively. These examining boards submit lists of questions from which the supervisors select those for the examination. The examinations are conducted by the examining boards and the results submitted to the supervisors, who issue the licenses.

Only graduates in medicine from colleges authorized by law to confer the degree of Doctor of Medicine are admitted to examination. If the diploma was issued after June 30, 1898, it must represent a four years' course. Examinations are held quarterly, commencing on the second Thursdays in January, April, July, and October of each year and continuing until the following Monday. Applications must be made on forms furnished by the Board of Medical Supervisors. They must be filed with the secretary of the Board at least two weeks prior to the day set for the examination which the applicant desires to enter. A fee of $10 must accompany each application.

Each candidate will be subjected to a written and oral examination. The branches covered by the examination are arranged in eight sections as follows: 1. Anatomy and histology; 2, physiology and hygiene; 3, chemistry, toxicology and medical jurisprudence; 4, pathology and bacteriology; 5, materia medica and therapeutics; 6, surgery and diseases of the eye and ear; 7, obstetrics and gynecology, and 8, practice of medicine. The written examination is divided into eight sessions of two hours each, extending over three days. The oral examination is held on the day or days immediately following. In the written examination ten questions are given in each session, and the answers must be complete within two hours. The examinations occur in the order above mentioned, subject, however, to change without notice. The oral examinations continue from day to day until finish. Licenses will be refused or revoked upon discovery of fraud or deception in passing examinations.

A general average of 75 per cent. will entitle the candidate to a license if in no section the percentage be less than 50; a candidate having a general average of 75 or more and having attained less than 50 in a single section, may, upon his request, be granted an immediate re-examination in that section. If, however, a candidate have less than 50 per cent. in more than one section, or less than 33.6 in any section, his application will be rejected, no matter what may be his general average. Midwives are also subject to examination before being licensed and registered. The law provides for revocation of license for fraud in passing examination, chronic inebriety, criminal abortion, crime involving moral turpitude and unprofessional or dishonorable conduct. Licenses must be recorded with clerk of district supreme court. The usual exemptions of government officials, outside consultants, emergency and domestic practice are provided for. The law contains a reciprocity clause. Executive officer of the board of health, Dr. William C. Woodward, Washington.

FLORIDA.

There are nine examining boards in Florida appointed by the governor, one for each judicial district and one each for the homeopathic and eclectics. These boards are expected "to examine thoroughly every applicant for certificate of qualification to practice medicine in any of its branches or departments, upon the production of his medical diploma from a recognized college or in the event said applicant shall have lost his diploma, or the same shall have been destroyed prior to the year 1870, then upon satisfactory evidence to such board of such loss or destruction, upon the following subjects: Anatomy, physiology, gynecology, surgery, therapeutics, obstetrics and chemistry, but no preference shall be given to any school of medicine: provided, that it shall be the duty of the board of homeopathic medical examiners to examine thoroughly every applicant for certificate of qualification to practice medicine in any of its branches or departments, upon the production of his diploma from a college recognized by the American Institute of Homeopathy, upon the following subjects: Anatomy, physiology, surgery, gynecology, materia medica, therapeutics, obstetrics and chemistry, and no preference shall be given to any school of medicine."

Any member of the several boards can grant a temporary certificate good till the next meeting. He must notify the secretary of the board of his action and the secretary notify the other boards. It is said that the law is not always alike efficient in all parts of the state and that temporary certificates are sometimes used as permanent ones.

GEORGIA.

There has been no change in the law approved Dec. 12, 1894. The law provides for the appointment by the governor of three separate boards of medical examiners. "One board to consist of five members of the regular school of medicine; one board of five members of the eclectic school of medicine, and one board of five members of the homeopathic school of medicine. The members of each of said boards shall be men learned in medicine and surgery, of good moral and professional character, and graduates of reputable medical colleges; but none of them shall be members of the faculty of any medical college. Each of said three boards shall be wholly independent of and separate from the other two in the performance of the duties herein required of each of said boards. A majority of each board shall constitute a quorum." Each board shall hold two regular meetings in each year. One meeting shall be held at such time, on or just before graduation day of each medical college now chartered, or that may hereafter be chartered in this state; and the board of examiners, after consultation with the faculty of said college, shall fix a time for its meeting to suit a majority of the students graduating from said college; the other on the second Tuesday in October.

"It shall be the duty of each board, at any of its meetings, to examine only applicants who are graduates of an incorporated medical college, school or university that requires not less than three full courses of study of six months each, who shall desire to commence the practice of medicine or surgery in the state; but any person from any other state who shall have graduated prior to April 1, 1895, at a lawfully chartered medical college requiring only two full courses of study, shall be eligible for examination and license; provided, always, that the applicant for such examination shall hold a lawfully conferred diploma from an incorporated medical college which conforms to the system of practice represented by the board to which the application shall be made, unless the applicant desires to practice a different system from that recognized in his diploma; then he shall appear before the board which represents the system that he proposes to practice. In no event shall an applicant who stands rejected by one of said boards be examined or licensed by either of the said boards. If the applicant desires to practice a system not represented by any of the boards hereby established, he may elect for himself the board before which he will appear for examination. When an applicant has passed a satisfactory examination the president thereof shall grant to him a certificate to that effect. A fee of $10 shall be paid to the board by each applicant before such examination is had. "In case an applicant shall fail to pass a satisfactory examination before any board, he shall not be permitted to stand any further examination before any of the boards within the next three months thereafter. Nor shall he again have to pay the fee prescribed as aforesaid for any subsequent examination; provided, that when, in the opinion of the president of any board, any applicant has been prevented by good cause from appearing before said board, the president and members of said board designated by him shall constitute a committee, who shall examine such applicant, and may, if they see fit, grant him a certificate which shall have the same force and effect as though granted by a full board, until the next regular meeting of the board, when, if the applicant fails to appear for examination, said certificate shall

be void. Any person shall be regarded as practicing medicine or surgery within the meaning of this act, who shall prescribe for the sick or those in need of medical or surgical aid, and shall charge or receive therefor money or other compensation or consideration, directly or indirectly; provided, however, that midwives and nurses shall not be regarded as practicing medicine or surgery."

Secretary board of medical examiners (regular), Dr. B. S. Holmes, Atlanta.

IDAHO.

The state board of medical examiners are appointed by the governor, and must not have a majority of any one school of medicine. The act of 1899 provides (Sec. 6) that: "After the passage of this act, every person, except as hereinafter provided, desiring to commence the practice of medicine and surgery, or either of them, within the state shall, immediately and prior to commencing same, make a written application to the state medical examining board, upon suitably prepared blanks, to be furnished by the board, for a license. The applicant shall transmit with said application his or her diploma, together with an affidavit that said diploma is genuine, and that the applicant is its rightful possessor and the identical person named therein, and that it was obtained by pursuing the regular course of study or examination, and setting forth that he or she is a citizen of the United States, or has declared intention of becoming such. If the diploma has been issued by a reputable college of medicine in good standing the applicant shall be eligible to examination. All applicants shall be examined in the applied branches of the theory and practice of medicine and surgery or either of them, as those branches are taught in the reputable chartered schools of the system of medicine to which the applicant belongs and which the applicant intends to practice and such examination shall in all cases include anatomy, physiology, pathology, diagnosis, hygiene, chemistry, histology and toxicology. No applicant for license shall be allowed to practice medicine and surgery, or either of them, until such license shall have been granted. The board shall cause the examination to be scientific and practical and sufficiently thorough to test the applicant's fitness to practice medicine and surgery, or either of them, and if the applicant correctly answer at least 75 per cent. of all the questions submitted, the board shall grant him a license to practice medicine and surgery in the state. Applicants must furnish sufficient evidence to the board that they are of good moral character. All applications under this section must be accompanied by $25, which is the fee for examination. Should the applicant fail to pass the examination, the fee is not returnable. In the case an applicant for an examination fails to pass the required examination, he or she may be re-examined after the expiration of six months, and within one year without the payment of an additional fee, and thereafter said applicant may be examined as often as desired at any regular or special meeting of the board on the payment of the regular fee for such examination. The board may also refuse a license, for unprofessional conduct, or conduct of a criminal, immoral, or dishonorable nature."

Section 7 defines what shall be considered "unprofessional or dishonorable conduct" including participation in criminal acts: employing "cappers" or "steerers," obtaining fees by professing to cure incurable diseases; violation of professional secrecy, advertising and intemperance.

"Any person shall be regarded as practicing medicine and surgery or either who shall advertise in any manner, or holds himself or herself out to the public as a physician and surgeon, or either, in this state, or who shall investigate or diagnosticate or offer to investigate or diagnosticate any physical or mental ailment of any person with a view of relieving the same as is commonly done by physicians or surgeons, or suggest, recommend, prescribe or direct, for the use of any person, sick, injured or deformed, any drug, medicine, means or appliance for the intended relief, palliation, or cure of the same, with the intent of receiving thereof, either directly or indirectly, any fee, gift or compensation whatsoever."

This does not include services rendered in cases of emergency, where no fee is charged. "Any person who shall present to the board, as his or her own, the diploma of another, or a forged affidavit of identification, or who shall attempt to personate another practitioner of a like or a different name, shall, upon conviction thereof, be subject to such fine and imprisonment as are made and provided by the statutes of the State of Idaho for the crime of forgery."

Section 16 gives the usual exemption of government officers, railway surgeons and outside consultants. Licenses must be recorded within thirty days with county recorder. Regular meetings of the board of the first Tuesday in April and October. Special meetings when called. Secretary, board of medical examiners, Dr. R. L. Nourse, Hailey.

ILLINOIS.

The regulation of medical practice is in the hands of the state board of health. The law enacts that:

"No person shall hereafter begin the practice of medicine or any of the branches thereof, or midwifery, in this state without first applying for and obtaining a license from the state board of health. Application shall be made in writing, and shall be accompanied by the examination fee specified, and with proof that the applicant is of good moral character. Applications from candidates who desire to practice medicine and surgery in all their branches shall be accompanied by proof that the applicant is a graduate of a medical college or institution in good standing as may be determined by the board. When the applicant has been inspected by the board and found to comply with the foregoing provisions, the board shall notify the applicant to appear before it for examination, at the time and place mentioned in such notice. Examinations may be made in whole or in part in writing by the board, and shall be of a character sufficiently strict to test the qualifications of the candidate as a practitioner. The examination of those who desire to practice any special system or science of treating human ailments who do not use medicines internally or externally, and who do not practice operative surgery shall be of a character sufficiently strict to rest their qualifications as practitioners. Provided, that graduates of legally chartered medical colleges in Illinois in good standing as may be determined by the board, may be granted certificates without examinations. If the applicant successfully passes his examination, or presents a diploma from a legally chartered medical college in Illinois of good standing, the board shall issue to such applicant a license authorizing him to practice medicine, midwifery or other systems of treating human ailments, as the case may be: Provided that those who are authorized to practice other systems can not use medicine internally or externally or perform surgical operations: Provided further, that only those who are authorized to practice medicine and surgery in all their branches shall call or advertise themselves as physicians or doctors; and provided further, that those who are authorized to practice midwifery shall not use any drug or medicine or attend other than cases of labor. Any wilful violation on the part of an applicant of any of the rules and regulations of the board, governing examinations shall be sufficient cause for the board to refuse to issue a license to such applicant. Such certificates shall be signed by all members of the board and attested by the secretary.

"Every person holding a certificate shall have it recorded in the office of the county in which he resides or practices within three months from its date, and the date of recording shall be endorsed thereon. Until such certificate is recorded, the holder shall not exercise any of the rights or privileges conferred therein. Any person practicing in another county shall record the certificate in like manner in the county in which he practices, and the holder of the certificate shall pay to the county clerk the usual fee for making the record. The fees for examination and for a certificate are $10 for examination in medicine and surgery, and $5 for a certificate if issued; $5 for an examination in midwifery, and $3 for a certificate if issued. For all other practitioners $10 for an examination and $5 for a certificate if issued. The state board of health may refuse to issue the certificates provided for in this act to individuals who have been convicted of the practice of criminal abortion, or who have by false or fraudulent representation, obtained or sought to obtain practice in their profession, or by false or fraudulent representation of their profession have obtained or sought to obtain money or any other thing of value, or who advertise under names other than their own, or for any other unprofessional or dishonorable conduct, and the board may revoke such certificates for like causes. Provided, that no certificate shall be revoked or refused until the holder or applicant shall be given a hearing before the board. Any person shall be regarded as practicing medicine, within the meaning of this act, who shall treat, or profess to treat, operate on or prescribe for any physical ailment or any physical injury to or deformity of another. Provided, that nothing in this section shall be construed to apply to the administration of domestic or family remedies in cases of emergency, or to the laws regulating the practice of dentistry or of pharmacy. And this act shall not apply to surgeons of the United States army, navy or marine-hospital service in the discharge of their official duties, or to any person who ministers to or treats the sick or suffering by mental or spiritual means, without the use of any drug or material remedy."

The law authorizes the board of health to exempt graduates of Illinois medical colleges from examination. It is not regarded as mandatory and by petition of the leading colleges the board has exercised its discretion in the matter and all graduates are alike examined. The last provision regarding treatment "by mental or spiritual means," etc., was inserted largely by "christian science" influence, and has been doubtless influential in some legal decisions. Thus the appellate court in one decision has practically defined the practice of medicine as confined to the administration of drugs, interpreting the concluding words of the above stated exemption as "By a familiar rule of construction the last clause means 'without the use of drug or like material remedy.'" On this interpretation of the law it was ruled that a "magnetic healer" who assumed the title of "Doctor" was not practicing medicine and therefore not liable to the penalty for illegal practice; contrary decisions have been made in other decisions of the appellate court. Another, a supreme court decision, makes it impossible to discipline any one for dishonorable or unprofessional conduct whose license was issued before the present law went into effect.

Board meets for examinations at Great Northern Hotel, Chicago, on the second Wednesday of January, April, July, and October. Secretary, state board of health, Dr. J. A. Egan, Springfield.

INDIAN TERRITORY.

The regulations as to medical practice vary according to local laws in the different tribal organizations and are binding on their members. Those not members of the different tribes or Indian nations can reside there only on sufferance.

INDIANA.

The governor has the appointment of the state board of medical registration and examination of five members which must not include any professor or teacher in a medical college and "each of the four schools or systems of medicine having the largest numerical representation in the state shall have at least one representative on said board."

Examination is required of all applicants for license to practice medicine in Indiana except students matriculating in medical colleges in that state prior to January, 1901, and graduating and making application prior to Jan. 1, 1905. The board is required to make and record from time to time a schedule of the minimum requirements which must be complied with by applicants for examination for license to practice, before they shall be entitled to receive such license. The board shall establish and cause to be recorded a schedule of the minimum requirements and rules for the recognition of medical colleges, so as to keep these requirements up to the average standard of medical education in other states. "After the year 1897 no change shall be made in schedules of requirements in any year after the month of January of such year nor shall any change be made to have any retroactive effect, or that shall effect students theretofore matriculated. Such record shall be at all times open to examination by the public, and the said schedules of requirements after they have been established and recorded, and all changes made therein, shall be printed in circular form, and mailed to all medical colleges in the state, and shall also be furnished to any person upon application. Said board shall not in the establishment of the aforesaid schedule or requirements, discriminate for or against any school or system of

medicine, nor shall it prescribe what system or systems or schools of medicine, shall be taught in any of the colleges, universities or other educational institutions of the state. It shall have the power to make and establish all necessary rules and regulations for the reciprocal recognition of certificates issued by other states and to prevent unjust and arbitrary exclusions by other states of graduates of medicine from this state who have filled its requirements."

No certificate shall be issued to any person whomsoever until he shall have satisfied the board that he has graduated at a reputable medical college, maintaining a standard of medical education as prescribed and shall have passed a satisfactory examination as to his qualifications to practice. The applicant shall have the right to designate, in writing, at the time he files his application, the member of the board who shall conduct his first examination in materia medica, therapeutics, theory and practice of medicine, surgery, obstetrics and gynecology.

The board at its discretion may authorize the secretary to issue a temporary permit to an applicant for the interim from date of application until the next regular meeting of the board. The state board of medical registration and examination shall have the right to review the evidence upon which a license has been obtained, and if it shall be found that a license has been obtained by fraud or misrepresentation, the board may revoke such license. The board (may) refuse to grant a certificate to any person guilty of felony or gross immorality, or addicted to the use of liquor or drug habit to such a degree as to render him unfit to practice medicine or surgery. If any person holding a license under the provisions of this act shall be guilty of any of the above enumerated acts or shall have procured a certificate or license by fraud or misrepresentation, the board may, after notice and hearing, revoke any license which has heretofore been or may hereafter be issued to him, together with the certificate upon which such license has been or may be issued.

Appeal is provided for. Midwives also have license and if without diplomas, must pass a satisfactory examination. The usual exception is made as not discriminately against different systems and schools of medicine, midwives, United States surgeons, consultants, or physicians whose practice extends from a neighboring state, and medical students under a registered physician for a period of two years.

"Section 8. To open an office for such purpose or to announce to the public in any way, a readiness to practice medicine in any county of the state or to prescribe for, or to give surgical assistance to, or to heal, cure or relieve, or to attempt to heal, cure or relieve those suffering from injury or deformity, or disease of mind or body, or to advertise, or to announce to the public in any manner a readiness or ability to heal, cure or relieve those who may be suffering from injury or deformity, or disease of mind or body, shall be to engage in the practice of medicine, within the meaning of this act: Provided that nothing in this act shall be construed to apply or to limit in any manner the manufacture or sale of proprietary medicines. It shall also be regarded as practicing medicine within the meaning of this act, if any one shall use in connection with his or her name the words or letters "Dr.," "Doctor," "Professor," "M.D." or "Healer," or any other title, word, letter or designation intending to imply or designate him or her as a practitioner of medicine or surgery in any of its branches Provided that this act shall not be construed to apply to non-itinerant opticians who are at this time engaged in the practice of optometry in this state nor to professional or other nurses."

The board may grant limited certificates which shall authorize the proper clerk to issue to the holder a license to practice osteopathy only. Such certificates shall be issued on the same terms and conditions as others, except that the applicant therefor shall not be required to pass an examination in materia medica nor shall the college from which he presents a diploma be required to conform to the standard fixed as to instructions in materia medica, but such college shall so conform in all other branches of instruction. Such license shall not authorize the holder to administer or to prescribe or use on any other than himself any drugs or medicines, and any such administration, prescription or use of any drug or medicine by the person holding such limited license shall be practicing medicine without a license, and such person shall be punished therefor as others are punished for practicing medicine without a license.

Fee for examination $25, good also for one other examination within the year. Fee for examination of midwives $10. Certificate must be recorded with county clerk in county of residence. Regular meetings of board at Indianapolis on the second Tuesday of January and July of each year. Special meetings as necessary. Secretary, board of medical registration and examination, Dr. W. F. Curryer, 42 E. Ohio St., Indianapolis.

IOWA.

The following is taken from the circular of information of the Iowa State Board of Medical Examiners:

"Section 2576 makes the physicians of the state board of health (seven, including two homeopaths and one eclectic, appointed by the governor), the board of medical examiners, and the secretary of the former board the secretary of the latter; provides for meetings in May and November and oftener if deemed necessary; provides for issuing a certificate upon proper application and prescribes the fee therefor. It prescribes the method of examination, and states that a failure to pass the examination will entitle the candidate to a re-examination without additional fee. Section 2577 requires that before beginning the practice the certificate shall be registered with the county recorder of the county in which the holder thereof resides, and in any other county of the state to which he may remove to practice. The fee for such record is fifty cents. Section 2578 declares that a certificate may be refused to any one otherwise qualified who is not of good moral character; and for like cause, or incompetency, or habitual intoxication, or upon proper evidence that a certificate had been granted upon false or fraudulent statements as to graduation or length of practice, may revoke the same; provided that such revocation can only be made by an affirmative vote of at least five members of the board, and this number shall embrace at least one or more members of the different schools of practice of the board; and further, that the standing of a legally chartered medical school can only be questioned by a like vote. Section 2579 says that anyone shall be regarded as a physician under the meaning of the law who shall publicly profess to be a physician, surgeon or obstetrician, and assume the duties thereof, or who shall make a practice of prescribing and furnishing medicine for the sick and who shall publicly profess to cure or heal. The following persons are exempt from the provisions of the law: Medical students who have attended not less than two full courses of lectures in a reputable medical college, who may prescribe under the supervision of a preceptor or gratuitous services in cases of emergency: surgeons of the United States army, navy, or marine-hospital service; physicians and midwives who have previously obtained certificates on length of practice without diploma or examination; physicians who, without such certificate, have been in practice in Iowa for five consecutive years, three years in one locality; registered pharmacists, filling prescriptions; advertising or selling patent or proprietary medicines or natural mineral waters flowing from wells or springs.

"Section 2580 prescribes penalties as follows For presenting to the board of medical examiners a fraudulent or false diploma, or one of which the holder is not the rightful owner, in order to procure a certificate; or for filing or attempting to file with the county recorder the certificate of another; or for practicing without obtaining and recording the required certificate; or for continuing to practice after the certificate has been revoked—unless embraced in the exceptions of section 2579—the offense is declared a misdemeanor, and the fine not less than $300 or more than $500 and imprisonment in the county jail until such fine is paid. Any one who shall attempt to file with the county recorder the certificate of another person, with the name of the party to whom it was issued erased and the claimant's name inserted, or shall attempt to file with the board of medical examiners any false affidavit of identification, shall be guilty of forgery. Section 2581 declares an itinerant physician to be a physician practicing medicine, surgery or obstetrics, or professing or attempting to treat, cure or heal diseases, ailments or injuries by any medicines, appliance or method, who goes from place to place, or from house to house, or by circulars, letters or advertisements asks persons to meet him for such treatment at places other than at his office at his place of residence and requires all such, in addition to the ordinary physician's certificate, to procure an itinerant's license from the state board of medical examiners, for which he shall pay to the state treasurer the sum of $250 per annum. The penalty for itinerating without such license is the same as for practicing as a physician without a certificate. The board may, for cause, refuse to issue such license, or having issued it, may revoke it for incompetency or gross immorality. This section does not prevent a physician from attending patients in any part of the state, to whom he may be called in the regular course of business, nor from consulting with other physicians.

"Section 2582 provides that after Jan. 1, 1899, no person can begin the practice of medicine in Iowa, excepting upon examination; that no person can be admitted to examination except upon graduation from a medical college recognized by the board as of good standing, and that no college can be so recognized by the board that does not require of those graduating after Jan. 1, 1899, attendance upon four full courses of study of not less than twenty-six weeks each, no two of which courses shall have been given in any one year, as a condition of such graduation. This section was amended by the 28th G. A. so as to require the board of medical examiners to examine the graduates of Iowa medical colleges who desire certificates at the time of graduation and at the place where the college is located. The fee for examination was reduced from $20 to $10. Section 2583 provides for the payment of $8 per day to the members of the board for each day actually spent in the work of the board, and a salary of $25 per month for the secretary," in addition to his salary as secretary of the state board of health. The board meets for examining candidates for license at Des Moines two weeks before the first Wednesdays of February, May, August and November. Secretary state board of medical examiners, Dr. J. F. Kennedy, Des Moines.

KANSAS.

The law passed March 22, 1901, provides for the appointment of a board of registration and examination of seven members, no one school of medicine to have a majority, and that "All persons intending to practice medicine, surgery or osteopathy after the passage of this act shall apply to said board at any regular meeting, or any other time or place as may be designated by the board, for a license. Application shall be made in writing, and shall be accompanied by the fee specified, together with the age and residence of the applicant, proof that he or she is of good moral character, and satisfactory evidence that he or she has devoted not less than three periods of six months each, no two within the same twelve months, or after Jan. 1, 1902, four periods of not less than six months each, no two in the same twelve months, to the study of medicine. Candidates shall submit to an examination of a character to test their qualifications as practitioners of medicine or surgery, and which shall embrace all those topics and subjects a knowledge of which is generally required by reputable medical colleges of the United States for the degree of Doctor of Medicine: provided that the examination in materia medica and therapeutics and in the theory and practice of medicine shall be conducted by those members only of the board who are of the same school of practice as the applicant claims to follow; provided, further, that graduates of legally chartered medical institutions of the United States or foreign countries in good standing, as determined by the board, may be, at the discretion of the board, granted a license without examination; * * * provided, further, that the board may in its discretion accept, in lieu of examination or diploma, the certificate of the board of registration and examination of any other state or territory of the United States or any foreign country whose standards of qualification for practice are equivalent to those of this state.

"Section 4. Upon the completion of the examination or the acceptance of the diploma or certificate as herein provided, the said board shall, if it finds the applicant qualified, grant a certificate to said applicant to practice medicine and surgery within this state, and which shall be signed by the president and secretary and attested by the seal of the board. Within thirty days of the date of any certificate of license issued by the board, the owner shall have

it recorded in the office of the clerk of the county in which he resides, or if a non-resident of this state, then of the county in which he has an office or intends to practice, and the date of the recording shall be endorsed thereon; and until such certificate or license is recorded he shall not exercise any of the rights or privileges conferred. The county clerk shall keep in a book for the purpose a complete list of the certificates recorded by him, which books shall be open to public inspection during business hours."

Fee for examination must not exceed $15; that for examining diploma or certificate from another state must not exceed $10.

Section 6 defines the practice of medicine and states the exemptions as follows: "Any person shall be regarded as practicing medicine and surgery within the meaning of this act who shall prescribe or who shall recommend for a fee for like use, any drug or medicine, or perform any surgical operation of whatever nature for the cure or relief of any wounds, fracture or bodily injury, infirmity or disease of another, or who shall use the words or letters "Dr." "Doctor," "M.D.," or any other title in connection with his name which in any way represents him as engaged in the practice of medicine and surgery; but nothing in this act shall be construed as interfering with any religious beliefs in the treatment of disease, provided that quarantine regulations relating to contagious diseases are not infringed upon. All persons who practice osteopathy shall be registered and licensed as doctors of osteopathy as hereinbefore provided, but they shall not administer drugs or medicines of any kind, nor perform operations in surgery."

The other usual exemption is also made of government officers, outside consultants, gratuitous services and domestic medicines.

Section 7 provides penalties for illegal practice, making it a misdemeanor subject to fine of not less than $50 or more than $200 for each offense. Board meets on second Tuesday of February, June and October, and one other meeting, time not stated. Secretary board of medical registration and examination, Dr. Henry W. Roby, Topeka.

KENTUCKY.

The medical law, as amended in 1898, provides:

"Section 3. Authority to practice medicine shall be a certificate from the state board of health, which board shall, upon application, issue a certificate to any reputable physician who is practicing or who desires to begin the practice of medicine in this state, who possesses any of the following qualifications: 1. A diploma from a reputable medical college legally chartered under the laws of this state. 2. A diploma from a reputable and legally chartered medical college of some other state or country, indorsed as such by the state board of health (only such as meet the minimum requirements of the American Medical College Association). 3. Satisfactory evidence from the person claiming the same that such person was reputably and honorably engaged in the practice of medicine in this state prior to Feb. 23, 1864. 4. Satisfactory evidence from any person who was reputably and honorably engaged in the practice of medicine in this state prior to Feb. 23, 1884, who has passed a satisfactory examination before said board. Applicants may present their credentials by mail or proxy, and the board shall issue its certificates to such applicants as are entitled thereto as though the applicant was present. All certificates shall be signed by the president and secretary, and attested by the seal of the board, and not more than $2 shall be charged for any certificate.

"Section 4. Nothing in this law shall be construed as to authorize any itinerant doctor to register or to practice medicine in any county in this state.

"Section 5. The state board of health may refuse to issue the certificate provided for in Section 3 of this article to any individual guilty of grossly unprofessional conduct of a character likely to deceive or defraud the public, and it may, after due notice and hearing, revoke such certificate for like cause. In all cases of refusal or revocation the applicant may appeal to the governor, who may affirm or overrule the decision of the board, and this decision shall be final."

"Section 7. It shall be the duty of the state and local boards of health to bring to the attention of the courts any violations of the provisions of this law within their respective jurisdictions.

"Section 8. Any person living in this state, or any person coming into this state, who shall practice medicine, or attempt to practice medicine in any of its branches, or who shall treat or attempt to treat any sick or afflicted person by any system or method whatsoever, for reward or compensation, without first complying with the provisions of this law, shall, upon conviction thereof, be fined $50, and upon each and every subsequent conviction shall be fined $100 and imprisoned thirty days, or either or both, in the discretion of the court or jury trying the case; and in no case where any provision of this law has been violated shall the person so violating be entitled to receive any compensation for the services rendered. To open an office for such purpose, or to announce to the public in any way a readiness to treat the sick or afflicted shall be deemed to engage in the practice of medicine within the meaning of this act."

The usual exceptions are made in not discriminating against particular systems or schools of medicine, midwives, U. S. surgeons, etc.

Certificates must be recorded with county clerk; fee for recording, 50 cents. Secretary state board of health, Dr. J. N. McCormack, Bowling Green.

LOUISIANA.

Louisiana requires a diploma from a medical college in good standing as determined by the state boards (regular and homeopathic appointed by the governor on recommendation of the state societies) of medical examiners and a satisfactory examination. The applicant must also satisfy the board that he or she is over 21 years old, of good moral character, and possesses at least a fair primary education. Certificates must be recorded with county clerk.

"Section 13. Be it further enacted, etc., That any person shall be regarded as practicing medicine, in any of its departments, within the meaning of this act, who shall append the letters "M.D." of "M.B." to his or her name, or repeatedly prescribe or direct, for the use of any person or persons, any drug or medicine or other agency for the treatment, cure or relief of any bodily injury, infirmity, or disease. This act shall not apply to farmers, and planters when exclusively practicing, without compensation, on their employes and tenants."

Fee for examination, $10, one-half refunded if no certificate is given. For certificate, $1. For temporary permit, $5, credited on examination fee. Midwives must be also examined for license; fee for certificate, $5; plantation and rural midwifery excepted. The usual exemptions are made for army, navy, and marine-hospital surgeons, and consultants from other states. Board meets at least twice a year, generally at New Orleans. Secretary state board of medical examiners, Dr. F. A. Larue, 624 Gravier St., New Orleans.

MAINE.

The examining board, known as the board of registration, was created by an act passed in 1895. The board consists of six persons appointed by the governor; they serve six years each. Members of this board can not belong to the faculty of any medical college or university, "and not more than two members of said board shall at one time be members of any one chartered state medical society." The fees taken in by the board go into the state treasury. The compensation of members of the board is $5 per day for actual time spent, and 5 cents per mile traveling expenses, the secretary getting additional compensation for books, stationery, postage, etc. The act of 1895 provided for registration on passage of a satisfactory examination, but this was amended March 22, 1901, so that hereafter all who apply for registration as physicians and surgeons must be examined and also have a diploma. Each applicant at least seven days before date of his examination must present to the secretary of the board certain information in regard to preliminary education, character, age, etc., and evidence of having graduated from some reputable medical school or college having power to confer degrees in medicine. The examination covers anatomy, physiology, pathology, materia medica, therapeutics, surgery, principles and practice of medicine and obstetrics.

It is "illegal for any person not duly registered by this board to practice medicine or surgery, or any branch thereof for gain or hire within this state. Whoever not being registered as aforesaid shall so practice or shall advertise or hold himself out to the public as a physician or surgeon in this state who appends to his name the letters M.D., or who uses the title of doctor or physician, meaning thereby a doctor of medicine, shall be punished by a fine of not less than $100, nor more than $500 for each offense, or by imprisonment in jail for three months, or both."

"Section 2. Neither shall this act apply to clairvoyants or the persons practicing hypnotism, magnetic healing, mind cure, massage, christian science, so called, or any other method of healing if no poisonous or dangerous drugs are employed nor surgical operations performed; provided, such persons do not violate any of the provisions of section 9 of this act in relation to the use of M.D. or the title of doctor or physician.

The following new rules have recently been passed by the board:

RULE 8. All medical schools and colleges legally chartered by the states in which they exist, and having the power given them by the state to confer the degree of Doctor of Medicine, and having an unchallenged reputation for honest teaching, and granting of diplomas, only after a proper time of study and an examination in all the branches with a rating averaging, at least 75 per cent, shall be considered as "reputable schools or colleges," and in good standing.

RULE 9. The minimum grade of preliminary education before admission to the study of medicine which the board will approve is a good English education, evidenced by a knowledge of English orthography and composition, mathematics, including algebra and plane geometry, geography, history, natural philosophy or physics and chemistry, with some laboratory work; and also the ability to read at sight common Latin prose. A college degree, a diploma from some normal school, high school, or academy, or a successful entrance examination to any recognized college will be accepted as evidence of the above. All others must pass an examination.

RULE 10. The standard of medical instruction which the board will approve is three years of medical study and three courses of lectures for those who graduated previous to 1902, and four years study and four courses of lectures after 1901. Five years of reputable practice before 1901 will be accepted in lieu of one year's study. Colleges or medical schools complying with these rules 9 and 10, will be approved by the board as far as preliminary and medical instruction is concerned.

The board has also adopted this year a rule regulating reciprocity of licensure as authorized by the act. A special circular and form of application is devised giving the conditions, which, with other forms, etc., must be obtained from the secretary. Fee for examination, $10. Regular meetings of the board are held in March, July and November of each year and such additional meetings at such times and places as it may determine. Secretary board of registration of medicine, Dr. A. K. P. Meserve, Portland.

MARYLAND.

There are two boards of medical examiners in Maryland, one representing the Medical and Chirurgical Faculty of Maryland and the other the State Homeopathic Medical Society. This fact should be considered in comparing the results of examinations. The law as last amended provides:

"Physicians and surgeons of good moral and professional standing who shall hereafter come into this state with the intent to follow the practice of medicine and surgery, graduates of a medical college or university of good standing or having a certificate or license from a board of medical examiners of any state where the requirements for practice are equal to those required by the board named in this article, may make application to the president of either board of medical examiners of this state, which application shall be made under oath and shall state when and how long the applicant has been engaged in the practice of medicine and surgery and from what medical college, university or other institution of learning he or she graduated. The board of medical examiners shall have the authority and discretion to require the applicant to undergo an examination, or may require said applicant to submit to a special examination, the terms and methods of which shall be prescribed by the board of medical examiners, and upon paying the fee for examination. After the examination and determination of the board that said applicant is qualified to practice medicine and surgery, and entitled to a license, a license shall be issued, which shall be filed and recorded

and it shall be then the duty of the clerk and of the court to register the name of the person so licensed as physician or surgeon, or both, in accordance with the provisions of the act."

The term, "practicing medicine or a practitioner of medicine," when used with respect to the qualification of a practitioner or applicant to be registered under this article, shall be construed to mean the practice of medicine as a profession or means of livlihood and by one duly licensed or registered. It shall be the duty of the secretary of either or both of said state boards of medical examiners to inquire into all violations of law under this article and to institute all proceedings or prosecutions, and all expenses incurred by any secretary of either of such boards shall be allowed and paid out of the funds acquired by or belonging to said boards. Section 41 requires a diploma from a school in which attendance on three annual courses of lectures is necessary for graduation. Examinations are written and cover the subjects of anatomy, physiology, chemistry, surgery, practice of medicine, materia medica and therapeutics, obstetrics, gynecology, pathology, medical jurisprudence and hygiene. Section 44 provides:

"That all examinations shall be conducted in such manner that the name, school of graduation and preparatory training of said applicant shall not be made known to the board of examiners until his examination papers have been graded. An applicant receiving a majority of the votes of the board before whom the applicant appears shall be considered to have passed a satisfactory examination and entitled to the license of said board." Fee for examination $10. License must be recorded with circuit clerk. Fee for recording $1.

Secretary, board of medical examiners (regular), Dr. J. M. P. Scott, Hagerstown.

Exception to these statutes are provided for United States surgeons, consultants, those practicing temporarily under a preceptor, midwives and gratuitous service in an emergency.

MASSACHUSETTS.

In Massachusetts the board of registration in medicine appointed by the governor has full charge of the regulation of admission to practice. Applications for registration are received only when made upon blanks furnished by the board, and signed and sworn to by the applicant. The law is mandatory that all must be examined; therefore certificates of registration by other state boards, or diplomas of graduation, can not be received in lieu of an examination. No special dates, other than the regular meetings of the board, are assigned for examinations, but seasonable notice will be sent to those whose applications are on file, as to date and place of special examinations. All candidates must be examined; the fee is $20. The latest legislation is as follows:

"Section 1. The examination for registration as physicians and surgeons under the provisions of chapter 458 of the acts of the year 1894, and acts for the amendment thereof and in addition thereto, shall be in whole or in part in writing in the English language, and shall be of scientific and practical character. They shall include the subjects of anatomy, surgery, physiology, pathology, obstetrics, gynecology, practice of medicine and hygiene, and shall be sufficiently thorough to test the applicant's fitness to practice medicine.

"Section 2. Any applicant failing to pass an examination satisfactory to the board of registration in medicine, and therefore refused registration, shall be entitled, within one year after such refusal, to a re-examination at a meeting of the board called for the examination of applicants, without the payment of an additional fee; but two such re-examinations shall exhaust his privilege under his original application.

"Section 3. Any person who, not being then lawfully authorized to practice medicine within this commonwealth and so registered according to law, shall hold himself out as a practitioner of medicine, or shall practice or attempt to practice medicine in any of its branches, within the limits of this commonwealth, shall be deemed guilty of a misdemeanor and shall be punished by a fine of not less than $100 nor more than $500 for each offense, or by imprisonment in jail for three months, or by both such fine and imprisonment; and in no case where any provision of this law has been violated shall the person so violating be entitled to receive compensation for services rendered."

After the usual exemptions of emergency service, domestic remedies, government officers, consultants, etc., it is specified:

"Nor shall this act apply to osteopathists, pharmacists, clairvoyants, persons practicing hypnotism, magnetic healing, mind cure, massage, christian science, or cosmopathic method of healing or to gratuitous prescribing by registered pharmacists: provided, such persons do not violate any of the provisions of section 3 thereof."

Regular meetings of board are on second Tuesday of March, July and November each year. Secretary, board of registration, Dr. E. B. Harvey, State House, Boston.

MICHIGAN.

The board of registration in medicine, including five regulars, two homeopaths, two eclectics and one physio-medical, is appointed by the governor on recommendation of the respective state societies. Applications for registration and examination are received when made upon blanks furnished by the board and signed and sworn to by the applicant. The law is mandatory that all must be examined, except graduates of approved and designated colleges, a list of which is furnished the applicant. Therefore, certificates of registration by other state boards, or diplomas of graduation from colleges not listed, can not be received in lieu of an examination. No special dates other than the regular meetings of the board are assigned for examinations, viz., the second Tuesdays in June and October of each year, at Lansing. Until further notice, applicants under examination will be given ten questions each of the following subjects, viz., anatomy, chemistry, bacteriology, histology, pathology, physiology, practice of medicine, surgery, obstetrics, gynecology, hygiene and public health laws of Michigan, medical jurisprudence, toxicology, diseases of the eye and ear, therapeutics, mental and nervous diseases, minor surgery, surgical pathology, surgical anatomy. Registration is refused when the average thus obtained is less than 75 per cent. Persons refused registration by failure to pass an examination satisfactorily, may be re-examined at any regular meeting of the board. The fee for examination is $10, which must accompany the application.

Application for an examination or re-examination at any regular meeting of the board, should be made at least two weeks before the date of the same, to the secretary. Certificates of registration or a certified copy must be filed with county clerk.

The law does not apply to government officials in their regular duties, outside consultants, temporary assistance in cases of emergency, domestic administration of family medicines, nor to any legally qualified osteopath engaged in the practice of osteopathy under the provisions of act number 78 of the public acts of the State of Michigan of 1897, regulating and licensing the practice of osteopathy in the state.

"Section 9. When any person shall append the letters M.B. or M.D., or prefix the title "Dr.," or "Doctor," or any other sign or appellation in a medical sense to his name, it shall be *prima facie* evidence of practicing medicine and surgery within the meaning of this act."

Secretary, state board of registration, Dr. B. D. Harison, Sault Ste. Marie.

MINNESOTA.

The state board of medical examiners, nine in number, three of them homeopaths, is appointed by the governor. Each applicant for license is required to make an affidavit setting forth his age, place of residence, time and place of each course of lectures, and the date of graduation. If the applicant is a graduate in medicine, his affidavit must be corroborated by the exhibition of his diploma or a certificate from the dean of the medical college showing that he is a graduate. Applicants who are non-graduates are required to corroborate their affidavits by exhibiting their cards of attendance at lectures or by certificate from the dean.

Graduates prior to July 1, 1887, must present evidence of having attended two courses of lectures in different years, if their diploma dates later than July 1, 1887, and prior to Jan. 1, 1899, three courses are required, and if subsequent to Jan. 1, 1899, four courses. A fee of $10 must be paid at the beginning of the examination. The fee is not returned in case of failure. A general average of 75 per cent. must be attained. Candidates from all schools shall answer in common all questions submitted, except the questions on materia medica, which are adapted to the school of medicine accepted by the candidate. The answer papers upon subjects peculiar to any one school of medicine are sent to the members of this board who are representatives of such school.

"Any person shall be regarded as practicing within the meaning of this act who shall append the letters M.D. or M.B. to his or her name, or for a fee prescribe, direct or recommend for the use of any person any drugs or medicine, or other agency for the treatment, care or relief of any wound, fracture or bodily injury, infirmity of disease; provided, however, this act shall not apply to dentists. * * * This act shall not apply to commissioned surgeons of the United States army, or navy, to physicians or surgeons in actual consultation from other states or territories, or to actual medical students practicing medicine under the direct supervision of a preceptor."

Licenses must be recorded by the clerk of the district court in and for the county where the licensee resides. Fee for examination $10. Regular meetings of the board at the capital on first Tuesday of January, April, June and October. Secretary, state board of medical examiners, Dr. C. J. Ringnell, Minneapolis.

MISSISSIPPI.

Chapter 104, annotated code, 1892. "Every person who desires to practice medicine must first obtain a license to do so from the state board of health. If any person shall practice as a physician or surgeon, without having first been examined and obtained a license as required by law, he shall, on conviction, be fined not less than $20 nor more than $200, or be imprisoned in the county jail not exceeding thirty days. Every person who desires to obtain a license to practice medicine must apply therefor, to the state board of health and must be examined by said board touching his learning in the following branches of medicine only, viz., anatomy, chemistry, obstetrics, materia medica, physiology, pathology, surgery, and hygiene; and, if the applicant be found by the board, upon examination, to possess sufficient learning in said branches and be of good morals, the board shall at once issue to him a license to practice medicine, which shall be signed by each member who approves of its issuance. * * * Every person who shall apply for license to practice medicine, shall, before he will be entitled to be examined, pay a fee of $10.25, of which $10 are to be divided equally among those members of the board who attend and conduct the examination of the applicant, and 25 cents to be paid to the secretary of the board for filing and preserving the application for license. Every person who receives a license to practice medicine must file it in the office of the clerk of the circuit court of the county in which he resides within sixty days from the date of its issuance; otherwise it shall become void. The secretary of the state board of health may issue under his signature a temporary license to any one to practice medicine, which shall be valid until the next meeting of the board for examining applicants; and such license shall show that date of its issuance, otherwise it shall become void. Only one temporary license shall ever be issued to the same person, and it shall always be made to an individual and not to a partnership. The secretary shall be entitled to 25 cents for such license, and the same shall be recorded as a permanent license is required to be, under like penalty for failure." Secretary, state board of health, Dr. John F. Hunter, Jackson.

"Section 1. Chap. 79, Acts 1898. Be it enacted by the legislature of the State of Mississippi, that section 3246 of the annotated code of Mississippi be amended to read as follows: The state board of health shall meet at the capitol twice in each year, at such time as may be designated by the board, for the purpose of examining applicants for license to practice medicine, and shall continue in session until all applicants are examined and the examinations are approved or disapproved. All examinations as to applicant's learning shall be upon written questions and answers, and distinction shall not be made between applicants because of the different systems of schools of practice that may be chosen." The board has selected the second Tuesday in May and October to hold the examinations.

MISSOURI.

Extract from law, approved March 12, 1901, and taking effect June 16, 1901:

"Sections 3 and 4. All persons desiring to practice medicine or surgery in this state, or to treat the sick or afflicted as provided in section 1 of this act, shall appear before the state board of health at such time and place as the board may direct and shall be there examined as to their fitness to engage in such practice. All persons appearing for examination shall make application in writing to the secretary of said board thirty days before the meeting. They shall furnish satisfactory evidence of their preliminary qualifications, and shall also furnish evidence of good moral character. The medical examination may be in whole or in part in writing, and shall be of elementary and practical character, but sufficiently strict to test the qualifications of the candidate as a practitioner, and shall embrace the subjects of anatomy, chemistry, physiology, pathology, therapeutics, obstetrics, gynecology, surgery, practice of medicine, medical jurisprudence and hygiene, and such other branches as the state board may direct.

"The candidates shall be required to answer 75 per cent. of such questions as are asked him before being granted a certificate. Provided, however, that the examination of any applicant in therapeutics shall be conducted by the member or members of said board who represent the system of medicine of which said applicant has been a student. If there shall be no representative of the school or system of which the applicant has been a student, the examination in therapeutics shall be conducted by an examiner appointed for that purpose by the governor of Missouri, but all examinations other than that in therapeutics shall be conducted as heretofore provided in this act. The board of health shall issue to such persons as they find, upon examination, to possess the requisite qualifications, a license to practice medicine and surgery in accordance with the provisions of this act, and the state board of health shall not be permitted to favor any particular school or system of medicine, but all applicants shall be subjected to the same examination and the same degree of proficiency shall be required of all." The board shall examine persons applying for a license, although such persons can not speak the English language, the applicant in all such cases to pay the expense of an interpreter satisfactory to the board.

Section 4. Every person holding a license from the state board of health shall have it recorded in the office of the county in which he resides, and the record shall be endorsed thereon. And the clerk is authorized to charge a fee of $1 for recording each license for record. Any person removing to another county to practice medicine or surgery shall have his license recorded in the county in which he removes to, and the holder of said license shall pay said clerk of said county, the usual fee for making the record. The county clerk shall keep in a book for that purpose a complete list of the licenses recorded by him with the date of issue. Any person neglecting for twenty days to record his license as in this section provided after entering upon the practice, shall be guilty of a misdemeanor and on conviction thereof shall be fined not less than $10 nor more than $50, and on failure to record said license for thirty days after such conviction shall be liable to a fine of not less than $100."

Fee for examination $15, re-examination free within twelve months. License must be recorded within twenty days with the county clerk, fee $1; in St. Louis with the health commissioner. Board meets for examinations quarterly, on January 1 of each year at Jefferson City, and at other points as the president and members of the board select. Secretary, state board of health, Dr. William F. Morrow, Kansas City.

MONTANA.

The state board of medical examiners is appointed by the governor. The medical practice act reads:

"Section 3. Every person hereafter wishing to practice medicine or surgery in any of their departments in this state, shall apply to said board for a certificate so to do. Every person applying shall present his or her diploma to the said board of examiners for verification as to its genuineness; and if the diploma is found genuine and is issued by a medical school legally organized and in good standing, whose teachers are graduates of a legally organized school, which facts the said board of examiners shall determine, and if the person representing and claiming said diploma be the person to whom the same was originally granted, at a time and place designated by said board, or at a regular meeting of said board, said applicant shall submit to an examination in the following branches, to-wit: anatomy, physiology, chemistry, histology, materia medica, therapeutics, preventative medicine, practice of medicine, surgery, obstetrics, diseases of women and children, diseases of the nervous system, diseases of the eye and ear, medical jurisprudence, and such other branches as the board shall deem advisable, and present evidence of having attended four courses of at least six months each, but such evidence of attending such four courses of lectures shall not be required of applicants graduating prior to July 1, 1898; said board shall cause such examination to be both scientific and practical, but of sufficient thoroughness and severity to test the candidate's fitness to practice medicine and surgery; when desired such examination may be conducted in the presence of the dean of any medical school, or the president of any medical society of this state. After examination such board shall, if the candidate has been found qualified, grant a certificate to such candidate to practice medicine and surgery in the state of Montana; which said certificate can only be granted by the consent of not less than four members of the said board, and which certificate shall be signed by the president and secretary of said board and attested by the seal thereof: Provided, however, that during the intervening period of the sessions of the board, any person desiring to practice medicine in this state may present his or her diploma to the president or secretary of the board, who may issue a certificate good until the next regular meeting of the board."

"Section 5. Every person obtaining a certificate from the board must, within 60 days from the date thereof, have the same recorded in the office of the county clerk in the county wherein he resides. If he removes from one county to another to practice medicine or surgery, his certificate must immediately be recorded in the county to which he removes."

"Section 6. This act shall not apply to mid-wives of skill and experience, commissioned surgeons of the United States army and navy in the discharge of their official duties, nor to physicians and surgeons in actual consultation from other states and territories." Fee for examination $15. Re-examination on failure, within six months, free. Secretary William C. Riddell, Helena, state board of medical examiners. Examinations, first Tuesdays in April and October of each year.

NEBRASKA.

The state board of health, composed of the governor, attorney-general and superintendents of public instruction, appoints four "secretaries," graduated physicians of at least seven consecutive years of practice, to assist and advise the board granting certificates for licenses to practice medicine and prosecution of all violations of the medical practice law. Two shall be regular physicians, one homeopathic and one eclectic. The "secretaries" are in reality the board of health: the method adopted is to get around the constitution, which forbids the creation of more "boards."

"Section 7. It shall be unlawful for any person to practice medicine, surgery or obstetrics or any of the branches thereof, in this state, without first having obtained and registered the certificate provided for by this act; and no person shall be entitled to the certificate herein provided for unless he shall be a graduate of a legally chartered medical school or college in good standing; said qualifications to be determined by the board. Provided, however, that nothing in this act shall be construed to prevent physicians residing in other states from visiting patients in consultation with resident physicians who have complied herewith."

"Section 8. The term 'medical school or college in good standing' shall be defined as follows, to wit: a medical school or college requiring a preliminary examination for admission to its course of study in all the common branches, and in Latin and in the higher mathematics, which requirements shall be regularly published in all the advertisements and in each prospectus or catalogue issued by said school, which medical school or college shall also require as a requisite for granting the degree of M.D. attendance upon at least four courses of lectures of six months each, no two of said courses to be held within one year, and having a full faculty of capable professors in all the different branches of medical education, to-wit: anatomy, physiology, chemistry, toxicology, pathology, hygiene, materia medica, therapeutics, obstetrics, bacteriology, medical jurisprudence, gynecology, principles and practice of medicine and surgery, and specially requiring clinical instruction in the two last named of not less than four hours per week in each during the last two courses of lectures: Provided that this 'four years' clause shall not apply to degrees granted, or to be granted, prior to August, 1898."

Section 9 provides that applicants must present their diplomas to the board, with the usual affidavit as to genuineness, and makes any misstatement in such perjury. Section 10 provides for the issuance of license and its recording with the county clerk in whatever county or counties the practice extends. The board can refuse or revoke certificates for cause, and no person not qualified can recover by law for medical services. Penalties: fine $50 to $300 and costs are prescribed for illegal practice.

Section 17 reads: "Any person shall be regarded as practicing medicine within the meaning of this act who shall operate or profess to heal or prescribe for or otherwise treat any physical or mental ailment of another. But nothing in this act shall be construed to prohibit gratuitous services in cases of emergency, and this act shall not apply to commissioned surgeons in the United States army and navy, nor to nurses in their legitimate occupations nor to the administration of ordinary family remedies." Section 18 prohibits itinerant nostrum vendors, etc. Fee for registration $10, which is used for compensation of the secretaries. Rules adopted by the Nebraska State Board of Health Feb. 3, 1898:

"Rule 1. That this board shall hereafter refuse to issue a state certificate to applicants who present diplomas from foreign countries as a basis for registration, unless the holder of said diploma has passed the state examination and received a certificate entitling him to practice medicine and surgery in the country in which his diploma was issued, or unless he is a licentiate of a recognized college of physicians and surgeons authorized to grant licenses.

"Rule 2. That in the future no certificate will be issued without letters of recommendation with regard to the moral and professional character of the applicant from at least two reputable medical men who live in Nebraska, or, if from non-residents of this state, such letters must be endorsed by reputable medical men of Nebraska."

The board meets on the first Thursday of each month at Lincoln Secretary of the board, Dr. Geo. H. Brash, Beatrice.

NEVADA.

The governor appoints a mixed board of medical examiners, which issues two forms of certificates, one for persons who present to it satisfactory diplomas or licenses, and the other for candidates who may be examined by the board, and "whenever a certificate is issued by said board, it shall notify the respective county clerks of the several counties within the state of the issuance of such certificate or certificates; and it shall be the duty of said clerks to keep and file said notices and also keep a list of the persons to whom issued.

"It shall also issue a certificate to any person who has had issued to him a diploma or license from any reputable school or college of medicine and surgery which is located without the United States, upon the applicant being found competent after having passed a satisfactory examination by the said board. When the board is not in session its secretary may issue a temporary certificate whenever the applicant shall have deposited the usual fee and filed his diploma or license with him, and such temporary certificate shall entitle the holder to practice until the next regular meeting of said board. And all examinations of applicants to practice shall be thorough and searching, and shall be in the following branches: Anatomy, physiology, chemistry, materia medica, therapeutics, principles and practice of medicine, principles and practice of surgery, gynecology, obstetrics, ophthalmology, path-

ology and all subjects relating to the practice of medicine and surgery. The board may judge whether the college or institution which issued any diploma or license presented to it is reputable and legally chartered and worthy of recognition, subject to the action of the courts in cases of abuse of its discretion in this respect."

The fee for certificate is $25. Certificates must be recorded with county recorder. "Any person shall be regarded as practicing medicine within the meaning of this act, who shall profess publicly to be a physician or surgeon, or who shall prescribe for the sick or profess to cure the sick by the administration of drugs or other means, or shall append to his name the letters M.D.; but nothing in this act shall be construed to prohibit any gratuitous services in cases of emergency, or to commissioned surgeons in the United States army or navy."

Regular meetings of the board occur on first Mondays in May and November. Secretary, state board of medical examiners, Dr S. L. Lee, Carson City.

NEW HAMPSHIRE.

The law provides for three boards of examiners, representing the regular, eclectic and homeopathic state societies. To be admitted to examination for license to practice medicine, the candidate must be over 21, of good moral character, have a college degree or education equivalent to a full course in a registered academy or high school, and have studied medicine not less than four full school years, including four satisfactory courses of not less than six months each in four different calendar years, and must either have received the degree of bachelor or doctor of medicine from some registered medical school, or a diploma or license conferring full right to practice medicine in some foreign country. Five or more years of reputable practice may be taken as equivalent for part of the preliminary education or four-course requirements, provided the substitution is stated in the license. The fee for examination is $10. Second examination permitted after six months' additional study without additional fee. Christian scientists, magnetic healers, clairvoyants, etc., exempted from provisions of this act, if they do not call themselves doctors or M.D.'s. The superintendent of public instruction, Channing Folsom, Concord, is the regent of the Board. Examination is at least twice a year, in June and December. The law contains a reciprocity clause, but it is not enforced, as it is not mandatory.

NEW JERSEY.

The board of medical examiners consists of five regular physicians, three homeopathic and one eclectic, appointed by the governor and confirmed by the senate. Examinations are held in the capitol, Trenton, on the third Tuesday and Wednesday in June and September. Application for the blank forms for examination should be made to the secretary and must be returned for approval and filing, with a fee of $25, at least ten days before the examination. Fee will be returned on failure to pass the examination. Requirements for admission to examinations: 1. Academic—a certificate of graduation in arts or sciences, or certified evidence of academic education equivalent to a high school course. 2. Medical—four years of medical study, including at least three courses of medical lectures in different calendar years in a legally incorporated medical college in good standing, prior to graduation in medicine. Only graduates in medicine are admitted to the examinations.

Subjects of examination: All examinations shall be written in the English language, and shall be held in the following subjects, namely, materia medica and therapeutics, obstetrics and gynecology, practice of medicine, including diseases of the skin, nose and throat; surgery, including surgical anatomy and diseases of the eye, ear and genito-urinary organs; anatomy; physiology; chemistry; histology, pathology and bacteriology; hygiene and medical jurisprudence. Candidates intending to practice homeopathy or eclecticism will be examined in materia medica and therapeutics by the members of the board of examiners representing those schools. Two hours are given to each section, in which ten questions are submitted. A total average of at least 75 per cent., or 675 points out of a possible 900, must be attained.

Endorsement of other state licenses: The license issued upon examination by a state board of medical examiners of another state may be endorsed by this board, in lieu of an examination, under the following conditions: 1. The candidate for endorsement must present with the application a duly attested certificate of academic education in conformity with the requirements. 2. The candidate must have studied medicine at least four years, including three courses of medical lectures in different calendar years in a legally incorporated medical college or colleges prior to receiving the degree of Doctor of Medicine. 3. The candidate must have passed a state examination of substantially the same kind and grade as that required by this board, and must have received a state license. 4. Candidate must have obtained a total average marking of at least 75 per cent. prior to receiving a state license. Candidates must designate the state license to be endorsed, and the acceptance of an application for the endorsement can not be determined until the forms provided by this board have been properly filled out and submitted for approval.

Application for endorsement of a medical license issued by another state examining board must be made upon a blank form provided by this board, and obtained of its secretary, and must be filled out in conformity with the above conditions respecting age, nativity, residence and academic and medical education; bear the seal of the medical institution from which the candidate was graduated, with the certificate of the dean or other executive officer; bear a verbatim copy of the applicant's state medical license over the seal of the state examining board issuing the same, together with the affidavit of the president and secretary thereof, as to date of examination, number of license, subjects examined and total average attained, and must be returned to the secretary of this board for approval and filing, with the affidavit of the candidate and a certified check or postal money order for the regular fee of $50. If approved, the license of this board will be issued within a few days, and the application form, with academic certificate, will be filed in the state library at Trenton. The endorsement of a college diploma can not be accepted in lieu of an examination. A certified copy of the license issued by this board must be filed with the clerk of the county in which the candidate intends to practice.

Any person hereafter commencing the practice of medicine and surgery in any of its branches in this state without first having obtained and filed a license from this board, shall be deemed guilty of a misdemeanor, and upon conviction thereof shall be punished for the first offense by a fine of not less than $100 or by imprisonment in the county jail for a period of not less than thirty days or by both fine and imprisonment, and for each subsequent offense the punishment shall be double that of the preceding one; and it shall be the duty of the respective district attorneys of the counties of this state to prosecute violation of the provisions of this act. All communications should be addressed to the secretary, E. L. B. Godfrey, M.D., Camden.

NEW MEXICO.

The Territorial board of health, composed of four regular physicians, two homeopaths and one eclectic, appointed by the governor, has charge of admissions to practice medicine.

"The board shall, upon the production of evidence satisfactory to it, license any person who is the holder of a diploma from a medical college in good standing, to practice medicine, surgery and obstetrics in New Mexico, and shall require all persons not the holders of such diplomas to pass such examination as to the board shall seem proper. In the verification of all diplomas and the conducting of all examinations, the president and secretary of said board shall be and are hereby empowered to administer oaths, and any person making a false oath or affidavit before said board, shall be deemed guilty of perjury, and be subject to punishment for that crime. Every person holding a certificate shall have it recorded in the office of the probate clerk of the county wherein the practitioner resides, within thirty days after said certificate is issued; it must be again recorded in any county to which the practitioner may remove permanently. The fact that no certificate shall be found in the county where any person is practicing or offering to practice medicine, shall be accepted by the court as prima facie evidence that no such certificate has been issued, and shall throw the burden of proving that he has a certificate upon the defendant in any suit or prosecution begun against him for the violation of the provisions of this act.

"For the purpose of this act, the words 'practice of medicine' shall mean to open an office for such purpose, or to announce to the public or to any private individual in any way, a desire or willingness or readiness to treat the sick or afflicted, or investigate or diagnose or offer to investigate or diagnose, any physical or mental ailment or disease of any person; or to suggest, recommend, prescribe or direct, for the use of any person, any drug, medicine, appliance or other agency, whether material or not material, for the cure, relief or palliation of any ailment or disease of the mind or body, or for the cure or relief of any wound, fracture or bodily injury or deformity, after having received, or with the intent of receiving thereof, either directly or indirectly, any bonus, gift or compensation. Provided, that nothing in this act shall be construed to prohibit gratuitous service in cases of emergency, or the domestic administration of family remedies, or women from practicing midwifery; and this act shall not apply to surgeons in the service of the United States in the discharge of their official duties."

Examinations will be required of all applicants to practice medicine in New Mexico, who shall have graduated after July, 1897, from any medical college which does not require of matriculants as a minimum evidence of sufficient general education, a high school certificate or its equivalent; and for graduation, proof of four years' study of medicine and four terms of lectures occurring in four separate years. The previous standard of three years' study and three terms of lectures in three separate years, with the preliminary requirement of matriculants of high school certificate, or its equivalent, will be maintained for all applicants who graduated between July 1, 1890, and July 1, 1897. According to a resolution of the territorial board of health adopted April 24, 1899, each applicant must furnish as references regarding moral character and professional standing, two or more names of reputable physicians, preferably the president and secretary of state licensing board, or president and secretary of state medical society where applicant last resided. Fee for certificate on diploma, $15; on examination, $25, not returnable. Applicants must present evidence of preliminary education with their diplomas. Meetings of board for examinations on first Mondays of June and December. Secretary of board of health, Dr. W. G. Hope, Albuquerque.

NEW YORK.

The regulation of admission to practice in New York is under the control of the Regents of the University, a body that has the oversight of educational matters in the state. It is composed of 19 regents elected for life by the legislature. The governor, lieutenant-governor, secretary of state and superintendent of public instruction are members ex-officio. The Regents appoint three state examining boards from lists furnished by the respective state medical societies, regular, homeopathic and eclectic, each appointee furnishing evidences of qualifications and of at least five years' practice in the state. Each board submits to the regents lists of suitable questions in anatomy, physiology and hygiene, chemistry, surgery, obstetrics, pathology and diagnosis, and therapeutics, including practice and materia medica. From these lists the regents prepare question papers for the examination which are the same for all candidates, "except that in therapeutics, practice and materia medica all the questions submitted to any candidate shall be chosen from those prepared by the board selected by that candidate and shall be in harmony with the tenets of the school as determined by its state board of medical examiners. The examinations are conducted by a regents' examiner, not a member of any of the several boards, and are exclusively in writing and in English. The questions and answer papers are examined by the respective examining boards and an official report on the same transmitted to the board of regents, signed by the president and secretary of the examining board, stating the standing of each candidate and recommending or not for license. The regents issue the licenses when they are satisfied the candidate is qualified.

"No person can practice medicine unless licensed and registered. To be admitted to examination for license the candidate (1) must be over 21, (2) of good moral character (certificate from two

physicians in good standing), (3) have the general education required preliminary to receiving the degree of bachelor or doctor of medicine in the state (48 academic counts—a good high school course at least); (4) have studied medicine not less than four full school years of at least nine months each, including four satisfactory courses of at least six months each in four different calendar years in a medical college registered as maintaining at the time a satisfactory standard; (5) has either received the degree of M.B. or M.D. from some registered medical school or a diploma or license entitling him to practice medicine in some foreign country. The regents may in their discretion accept as the equivalent for any part of the third and fourth requirement evidence of five or more years reputable practice, provided that such substitution is specified in the license."

The law contains a reciprocity clause, which has so far been inoperative, because it is held that other state requirements are not equal to those of New York in respect to the medical tests or the preliminary education requirements.

After Sept. 1, 1901, according to a regulation of the board of regents, a recent *photograph* of each candidate is required as a part of the application. The legislature has amended the law also so as to permit the regents to admit conditionally to examination in the subjects of anatomy, physiology, chemistry and hygiene, students who are 21 or over and have studied medicine not less than two years and attended two full courses in different years, under the same general conditions otherwise as in the final examination. Fee for examination, $25, payable in advance. Licenses must be recorded with the county clerk before beginning practice. The usual exemptions of government officials, consultants, etc., are included in the law. Secretary board of medical examiners, regular, Dr. Maurice J. Lewi, 102 West 81st St., New York. Secretary regents of the University, James Russell Parsons, State Capitol, Albany. The New York law does not contain a satisfactory definition of the practice of medicine. An attempt was made to remedy this at the last session of the legislature, but failed.

NORTH CAROLINA.

The board of examiners in North Carolina is appointed by the state medical society. The law as amended in 1899 provides that the board examine all applicants who exhibit a diploma, or furnish satisfactory proof of graduation, from a medical college in good standing requiring an attendance of not less than three years and supplying such facilities for clinical instruction as shall meet the approval of the board, for license to practice medicine or surgery, or any of the branches thereof, on the following branches of medical science, namely, anatomy, physiology, surgery, pathology, medical hygiene, chemistry, pharmacy, materia medica, therapeutics, obstetrics and the practice of medicine, and if on such examination they be found competent, to grant to each applicant a license or diploma, authorizing him to practice medicine and surgery, or any of the branches thereof: Provided, five members shall constitute a quorum and four of those present shall be agreed as to the qualifications of the applicant: Provided, that the requirement of three years' attendance shall not apply to those graduating prior to January first, 1900. Provided, further, that license or other satisfactory evidence of standing as a legal practitioner in another state shall be accepted in lieu of a diploma and entitled to examination.

To prevent delay and inconvenience, two members of the board of medical examiners may grant a temporary license to any applicant who shall comply with the requirements as to graduation prescribed and make report thereof to the next regular meeting of the board: Provided, such temporary license shall not continue in force longer than the next regular meeting of the board, and such temporary license shall in no case be granted after the applicant has been refused a license by the board of medical examiners.

The board of medical examiners shall assemble at the same time and place where and when the medical society assembles, and the said board shall remain in session from day to day until all the applicants who may present themselves for examination within the first five days after its meeting shall have been examined and disposed of: Provided, that the said board may, at its discretion, meet not more than one week before the said society, but always in the same place; and that one additional meeting in each year may be held at some suitable point in the state if deemed advisable. The board shall have power to demand of every applicant thus licensed the sum of $10 before issuing a license or diploma, and the sum of $5 for each temporary license, to be paid to the secretary of the board. Midwives and outside consultants are exempted. Licenses must be registered with the clerk of superior court of the county within 30 days after receiving same.

Secretary, board medical examiners, Dr. J. Howell Way, Waynesville. The next regular annual session will be held at Wilmington, N. C., in May, 1902.

NORTH DAKOTA.

The governor appoints the examining board, consisting of nine members, two of whom must be homeopaths and one a lawyer. Section 277 of the revised code of North Dakota provides that: "All persons before commencing the practice of medicine, surgery or obstetrics, in this state shall apply to the board for a license so to do, and such applicant shall submit to an examination in the following branches: Anatomy, physiology, chemistry, histology, materia medica, therapeutics, diseases of women and children, diseases of the nervous system, diseases of the eye and ear, medical jurisprudence and such other branches as the board deems advisable, and present evidence of having attended three courses of lectures of at least six months each; the board shall cause such examination to be practical and scientific and sufficient to test the candidate's fitness to practice medicine, surgery and obstetrics. If such applicant passes the prescribed examination, the board shall grant him a license to practice medicine, surgery and obstetrics in this state, which license shall be signed by the president and secretary of the board and attested by the seal thereof. The fee for such examination shall be $20, to be applied by the board toward paying the expenses thereof. The board may revoke or refuse a license for dishonorable or immoral conduct, chronic or persistent inebriety or for the practice of criminal abortion."

"Any person shall be regarded as practicing within the measures of this act, who shall append the letters M.D. or M.B. to his or her name or for a fee prescribe, direct or recommend for the use of any person any drug or medicine or other agency for the treatment, care or relief of any wound, fracture or bodily injury, infirmity or disease; provided, however, this act shall not apply to dentists." Surgeons in the United States army or navy, outside consultants, and medical students under supervision of preceptors, are also exempted.

Examinations held in Grand Forks, the first Tuesday in January, April, July and October of each year. Secretary, state board of medical examiners, Dr. H. M. Wheeler, Grand Forks.

OHIO.
